- I^b has the **local system symmetry** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$, implies that $I_\Sigma^b(\psi, \phi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$;

- I^b has the **global family symmetry in $\mathcal{I}$** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $I_\Sigma^b[\phi, \psi] \leq T$ implies $I_\Sigma^b[\psi, \phi] \leq T$;
- I^b has the **global system symmetry in $\mathcal{I}$** if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $I_\Sigma^b[\phi, \psi] \leq T$ implies $I_\Sigma^b[\psi, \phi] \leq T$.

The following proposition establishes a hierarchy of symmetry properties.

Proposition 684 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If I^b has the local family symmetry, then it has the local system symmetry in $\mathcal{I}$;*
- (b) *If I^b has the local system symmetry, then it has the global family symmetry in $\mathcal{I}$;*
- (c) *I^b has the global family symmetry if and only if it has the global system symmetry in $\mathcal{I}$.*

Proof: Part (a) and one of the implications in Part (c) follow directly from the fact that every theory system of $\mathcal{I}$ is also a theory family of $\mathcal{I}$.

For Part (b), suppose that I^b has the local system symmetry in $\mathcal{I}$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $I_\Sigma^b[\phi, \psi] \leq T$. Then by Lemma 93, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$I_{\Sigma'}^b[\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi)] \leq T.$$

This implies, by Lemma 99, that, for all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$I_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}.$$

Since I^b has the local system symmetry and, by Proposition 42, $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, we get that $I_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \text{SEN}^b(f)(\phi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'} \subseteq T_{\Sigma'}$. Since this holds for all $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\xi} \in \text{SEN}^b(\Sigma')$, we conclude that $I_\Sigma^b[\psi, \phi] \leq T$. Therefore I^b has the global family symmetry in $\mathcal{I}$.

Suppose, finally, that I^b has the global system symmetry in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $I_\Sigma^b[\phi, \psi] \leq T$. By Lemma 99, we get that $I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T}$. Since I^b has the global system symmetry and, by Proposition 42, $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, we get that $I_\Sigma^b[\psi, \phi] \leq \overleftarrow{T}$. Using again Lemma 99, we conclude that $I_\Sigma^b[\psi, \phi] \leq T$. Therefore, I^b has the global family symmetry in $\mathcal{I}$. ■

Proposition 684 has established the following hierarchy of symmetry properties:

We look, next, at some natural sufficient conditions under which some of these three symmetry properties coincide.

Proposition 685 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the local family and the local system symmetry coincide;*
- (b) *If I^b has only two arguments (i.e., is parameter free), then the local system symmetry and the global symmetry coincide.*

Proof: If $\mathcal{I}$ is systemic, then all theory families are theory systems and, hence, the local family and local system symmetries coincide.

Suppose, next, that I^b is parameter free and has the global system symmetry in $\mathcal{I}$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $I_\Sigma^b(\phi, \psi) \subseteq T_\Sigma$. Then, by Proposition 99, $I^b[\phi, \psi] \leq T$. Thus, by the global system property, $I_\Sigma^b[\psi, \phi] \leq T$, which implies that $I_\Sigma^b(\psi, \phi) \subseteq T_\Sigma$. Therefore, I^b has the local system symmetry in $\mathcal{I}$. ■

So in the case of a systemic π -institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter free set of natural transformations we have the hierarchy on the right.

Finally, for a systemic π -institution with a parameter free set of natural transformations all four symmetry properties collapse to a single one.

We provide some examples to show that the implications of Proposition 684 are not equivalences in general, i.e., in the 3-class hierarchy all inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding symmetry properties are proper inclusions.

We first present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that have the local system symmetry but not the local family symmetry in $\mathcal{I}$.

Example 686 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 1, & \text{if } (x, y) = (0, 1) \\ 0, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the local system symmetry in $\mathcal{I}$, but it does not have the local family symmetry in $\mathcal{I}$.

For the local system symmetry note that, if $T = \mathbf{SEN}^b$, then the defining implication is trivially true, whereas, if $T = \text{Thm}(\mathcal{I})$, then, since, for all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \psi) \neq 2$, the defining implication is vacuously true. So I^b has the local system symmetry in $\mathcal{I}$.

On the other hand, for $T = \{\{1, 2\}\} \in \text{ThFam}(\mathcal{I})$, we have $\sigma_\Sigma^b(0, 1) = 1 \in T_\Sigma$, but $\sigma_\Sigma^b(1, 0) = 0 \notin T_\Sigma$. Therefore, the implication defining local family symmetry fails for $T = \{\{1, 2\}\}$. So I^b is not locally family symmetric in $\mathcal{I}$.

Next, we present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that have the global family symmetry but not the local system symmetry in $\mathcal{I}$.

Example 687 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$ and $\mathbf{SEN}^b(f) : \{0, 1\} \rightarrow \{0, 1\}$ given by $0 \mapsto 1$ and $1 \mapsto 1$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^3 \rightarrow \{0, 1\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 0, & \text{if } (x, z) = (1, 0) \\ 1, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$. Note that both theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, are also theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the global family symmetry in $\mathcal{I}$, but it does not have the local system symmetry in $\mathcal{I}$.

For the global family symmetry note that, if $T = \mathbf{SEN}^b$, then the defining implication is trivially true, whereas, if $T = \text{Thm}(\mathcal{I})$, then, since, for all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\sigma_\Sigma^b(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi), 0) = \sigma_\Sigma^b(1, 1, 0) = 0,$$

the defining implication is vacuously true. So I^b has the global family symmetry in $\mathcal{I}$.

On the other hand, we have $\sigma_\Sigma^b(0, 1, \xi) = 1$, for all $\xi \in \mathbf{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(1, 0, 0) = 0 \notin \{1\}$. Therefore, the implication defining local system symmetry fails for $\text{Thm}(\mathcal{I})$. So I^b is not locally system symmetric in $\mathcal{I}$.

To close the study of symmetry properties, we prove that all three symmetry properties transfer from π -institutions to their models.

Proposition 688 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a symmetry property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, I has the corresponding symmetry property in $\mathcal{A}$.*

Proof: If I has a symmetry property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same symmetry in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I}, \mathcal{F}} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding symmetry in $\mathcal{I}$.

Suppose, conversely, that I^b has a symmetry in $\mathcal{I}$. We look at each of the three properties in turn.

- (a) Suppose I^b has the local family symmetry in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)},$$

for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$. Since this is equivalent to $\alpha_\Sigma(I_\Sigma^b(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}$, we get that $I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$. But, by hypothesis, I^b has the local family symmetry in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$. Therefore, we get that $I_\Sigma^b(\psi, \phi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. This now gives $\alpha_\Sigma(I_\Sigma^b(\psi, \phi, \vec{\xi})) \subseteq T_{F(\Sigma)}$, or, equivalently,

$$I_{F(\Sigma)}(\alpha_\Sigma(\psi), \alpha_\Sigma(\phi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}.$$

We conclude that I has the local family symmetry in $\mathcal{A}$.

- (b) The case of the local system symmetry can be proven similarly, taking into account that, if $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$.
- (c) Suppose that I^b has the global (family) symmetry in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that

$$I_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T.$$

Then, we have, by Lemma 95, $I_\Sigma^b[\phi, \psi] \leq \alpha^{-1}(T)$. Now, since, by hypothesis, I^b has the global family symmetry in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get that $I_\Sigma^b[\psi, \phi] \leq \alpha^{-1}(T)$, or, equivalently, by Lemma 95, $I_{F(\Sigma)}[\alpha_\Sigma(\psi), \alpha_\Sigma(\phi)] \leq T$. Thus, I has the global family symmetry in $\mathcal{A}$. ■

10.5 Transitivity

We study next various versions of the transitivity property, taking into account, again, both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that:

- I^b has the **local family transitivity in $\mathcal{I}$** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$ and $I_\Sigma^b(\psi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$, imply that $I_\Sigma^b(\phi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$;
- I^b has the **local system transitivity in $\mathcal{I}$** if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$ and $I_\Sigma^b(\psi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$, imply that $I_\Sigma^b(\phi, \chi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$;
- I^b has the **global family transitivity in $\mathcal{I}$** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b[\phi, \psi] \leq T$ and $I_\Sigma^b[\psi, \chi] \leq T$ imply $I_\Sigma^b[\phi, \chi] \leq T$;
- I^b has the **global system transitivity in $\mathcal{I}$** if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b[\phi, \psi] \leq T$ and $I_\Sigma^b[\psi, \chi] \leq T$ imply $I_\Sigma^b[\phi, \chi] \leq T$.

The following proposition establishes the hierarchy of transitivity properties.

Proposition 689 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If I^b has the local family transitivity, then it has the local system transitivity in $\mathcal{I}$;*
- (b) *If I^b has the local system transitivity, then it has the global family transitivity in $\mathcal{I}$;*
- (c) *I^b has the global family transitivity if and only if it has the global system transitivity in $\mathcal{I}$.*

Proof: The statement in Part (a) as well as one of the two implications of Part (c) follow from the fact that every theory system is also a theory family of $\mathcal{I}$.

For Part (b), suppose that I^b has the local system transitivity and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, such that $I_\Sigma^b[\phi, \psi] \leq T$

and $I_{\Sigma}^b[\psi, \chi] \leq T$. By Lemma 93, we get that, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$I_{\Sigma'}^b[\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi)] \leq T, \quad I_{\Sigma'}^b[\text{SEN}^b(f)(\psi), \text{SEN}^b(f)(\chi)] \leq T.$$

So, by Proposition 99, we get, for all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\begin{aligned} I_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), \vec{\xi}) &\subseteq \overleftarrow{T}_{\Sigma'}, \\ I_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \text{SEN}^b(f)(\chi), \vec{\xi}) &\subseteq \overleftarrow{T}_{\Sigma'}. \end{aligned}$$

By local system transitivity, we obtain $I_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\chi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}$. Since this holds for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma')$, we conclude that $I_{\Sigma'}^b[\phi, \chi] \leq T$. Therefore, I^b has the global family transitivity in $\mathcal{I}$.

Finally, suppose that I^b has the global system transitivity in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that $I_{\Sigma}^b[\phi, \psi] \leq T$ and $I_{\Sigma}^b[\psi, \chi] \leq T$. By Proposition 99, we get $I_{\Sigma}^b[\phi, \psi] \leq \overleftarrow{T}$ and $I_{\Sigma}^b[\psi, \chi] \leq \overleftarrow{T}$. Hence, by global system transitivity, $I_{\Sigma}^b[\phi, \chi] \leq \overleftarrow{T}$. Now, using Proposition 99 again, we conclude that $I_{\Sigma}^b[\phi, \chi] \leq T$. Therefore, I^b has the global family transitivity in $\mathcal{I}$. ■

Proposition 689 has established the following hierarchy of transitivity properties:

We also have the following result regarding natural sufficient conditions under which some of these three transitivity properties coincide.

Proposition 690 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the local family and the local system transitivity coincide;*
- (b) *If I^b has only two arguments (i.e., is parameter free), then the local system transitivity and the global transitivity properties coincide.*

Proof: If $\mathcal{I}$ is systemic, then all theory families are theory systems and the local family and local system transitivity properties collapse.

Suppose that I^b is parameter free and that I^b has the global (family) transitivity in $\mathcal{I}$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that $I_\Sigma^b(\phi, \psi) \subseteq T_\Sigma$ and $I_\Sigma^b(\psi, \chi) \subseteq T_\Sigma$. By Proposition 99, $I_\Sigma^b[\phi, \psi] \leq T$ and $I_\Sigma^b[\psi, \chi] \leq T$. Thus, by the global family transitivity property, $I_\Sigma^b[\phi, \chi] \leq T$, which implies that $I_\Sigma^b(\phi, \chi) \subseteq T_\Sigma$. We conclude that I^b has the local system transitivity in $\mathcal{I}$. ■

So in the case of a systemic π -institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter free set of natural transformations we have the hierarchy on the right.

Finally, for a systemic π -institution with a parameter free set of natural transformations all four transitivity properties collapse to a single one.

We provide some examples to show that the implications of Proposition 689 are not equivalences in general, i.e., in the 3-class transitivity hierarchy all inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding transitivity properties are proper inclusions.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the local system transitivity but not the local family transitivity in $\mathcal{I}$.

Example 691 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 1, & \text{if } (x, y) = (0, 1) \text{ or } (1, 2) \\ 0, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and SEN^b are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the local system transitivity in $\mathcal{I}$, but it does not have the local family transitivity in $\mathcal{I}$.

For the local system transitivity note that, if $T = \text{SEN}^b$, then the defining implication is trivially true, whereas, if $T = \text{Thm}(\mathcal{I})$, then, since, for all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \psi) \neq 2$, the defining implication is vacuously true. So I^b has the local system transitivity in $\mathcal{I}$.

On the other hand, for $T = \{\{1, 2\}\} \in \text{ThFam}(\mathcal{I})$, we have $\sigma_\Sigma^b(0, 1) = \sigma_\Sigma^b(1, 2) = 1 \in T_\Sigma$, but $\sigma_\Sigma^b(0, 2) = 0 \notin T_\Sigma$. Therefore, the implication defining local family transitivity fails for $T = \{\{1, 2\}\}$. So I^b is not locally family transitive in $\mathcal{I}$.

We now present an example to show that there is π -institution $\mathcal{I}$, with a set of natural transformations that has the global family transitivity but not the local system transitivity in $\mathcal{I}$.

Example 692 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 2$, $1 \mapsto 2$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^3 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 0, & \text{if } x = y = 0 \text{ or } x = y = 1 \\ 2, & \text{if } \{x, y\} = \{0, 1\} \text{ or } x = y = z = 2 \\ z, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that all four theory families, $\text{Thm}(\mathcal{I})$, $T = \{\{0, 2\}\}$, $T' = \{\{1, 2\}\}$ and SEN^b , are also theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the global family transitivity in $\mathcal{I}$, but it does not have the local system transitivity in $\mathcal{I}$.

For the global family transitivity note that, because, for all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), 0) = 0$ and $\sigma_\Sigma^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), 1) = 1$, the implication of the defining condition is vacuously true for $\text{Thm}(\mathcal{I})$, T and T' and trivially true for SEN^b . Therefore, we get that I^b has the global family transitivity in $\mathcal{I}$.

On the other hand, we have $\sigma_\Sigma^b(0, 1, \xi) = \sigma_\Sigma^b(1, 0, \xi) = 2$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(0, 0, 0) = 0 \notin \{2\}$. Therefore, the implication defining local system transitivity fails for $\text{Thm}(\mathcal{I})$. So I^b does not have the local system transitivity in $\mathcal{I}$.

We close the study of transitivity by providing, again, a transfer property for transitivity.

Proposition 693 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a transitivity property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding transitivity property in $\mathcal{A}$.

Proof: If I has a transitivity property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same transitivity in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I}, \mathcal{F}} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding transitivity in $\mathcal{I}$.

Suppose, conversely, that I^b has a transitivity property in $\mathcal{I}$. We look at each of the three properties in turn.

- (a) Suppose I^b has the local family transitivity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that, for all $\vec{\xi} \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} I_{F(\Sigma)}(\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi), \alpha_{\Sigma}(\vec{\xi})) &\subseteq T_{F(\Sigma)}, \\ I_{F(\Sigma)}(\alpha_{\Sigma}(\psi), \alpha_{\Sigma}(\chi), \alpha_{\Sigma}(\vec{\xi})) &\subseteq T_{F(\Sigma)}. \end{aligned}$$

These are equivalent, respectively, to

$$\alpha_{\Sigma}(I_{\Sigma}^b(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}, \quad \alpha_{\Sigma}(I_{\Sigma}^b(\psi, \chi, \vec{\xi})) \subseteq T_{F(\Sigma)},$$

i.e., to $I_{\Sigma}^b(\phi, \psi, \vec{\xi}) \subseteq \alpha_{\Sigma}^{-1}(T_{F(\Sigma)})$ and $I_{\Sigma}^b(\psi, \chi, \vec{\xi}) \subseteq \alpha_{\Sigma}^{-1}(T_{F(\Sigma)})$, for all $\vec{\chi} \in \text{SEN}^b(\Sigma)$. But, by hypothesis, I^b has the local family transitivity in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$. Therefore, we get that $I_{\Sigma}^b(\phi, \chi, \vec{\xi}) \subseteq \alpha_{\Sigma}^{-1}(T_{F(\Sigma)})$, for all $\vec{\chi} \in \text{SEN}^b(\Sigma)$. Thus, $\alpha_{\Sigma}(I_{\Sigma}^b(\phi, \chi, \vec{\xi})) \subseteq T_{F(\Sigma)}$ and, hence, $I_{F(\Sigma)}(\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\chi), \alpha_{\Sigma}(\vec{\xi})) \subseteq T_{F(\Sigma)}$. This, combined with the surjectivity of $\langle F, \alpha \rangle$, proves that I has the local family transitivity in $\mathcal{A}$.

- (b) The case of the local system transitivity may be proven similarly, taking into account that, if $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$.
- (c) Suppose that I^b has the global (family) transitivity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that

$$I_{F(\Sigma)}[\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi)] \leq T \quad \text{and} \quad I_{F(\Sigma)}[\alpha_{\Sigma}(\psi), \alpha_{\Sigma}(\chi)] \leq T.$$

Then, we have, by Lemma 95, $I_{\Sigma}^b[\phi, \psi] \leq \alpha^{-1}(T)$ and $I_{\Sigma}^b[\psi, \chi] \leq \alpha^{-1}(T)$. Since, by hypothesis, I^b has the global family transitivity in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get that $I_{\Sigma}^b[\phi, \chi] \leq \alpha^{-1}(T)$, or, equivalently, using again Lemma 95, $I_{F(\Sigma)}[\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\chi)] \leq T$. Thus, I has the global family transitivity in $\mathcal{A}$. ■

10.6 Equivalence

We look now at sets of natural transformations I^b , with two distinguished arguments, that define (modulo theory families) equivalence relation families on the underlying algebraic system of a π -institution $\mathcal{I}$. We assume that I^b has the reflexivity property and study combinations of possible symmetry and transitivity properties that the set of connectives may or may not possess.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^{\omega} \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. Let $X, Y \in \{\text{LF}, \text{LS}, \text{GB}\}$,

where LF stands for “Local Family”, LS stands for “Local System” and GB stands for “GloBal”. We say that I^b has the **XY -equivalence property in $\mathcal{I}$** if it has

- (a) reflexivity in $\mathcal{I}$;
- (b) X symmetry in $\mathcal{I}$ and
- (c) Y transitivity in $\mathcal{I}$.

Recall the following hierarchies of symmetry and transitivity properties that were established in Sections 10.4 and 10.5, respectively:

From these, we can infer the following hierarchy of equivalence properties:

Corollary 694 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. The nine equivalence properties constitute the hierarchy depicted in the accompanying diagram.*

Proof: The statement is a direct consequence of Propositions 684 and 689.

■

Based on the analysis performed on symmetry and transitivity, we have the following result regarding natural sufficient conditions under which some of the nine equivalence properties above coincide. We let LC stand for “Lo-Cal” to summarize the case when the local family and the local system version of a property coincide.

Corollary 695 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the equivalence hierarchy collapses to the one depicted below;*

- (b) *If I^b has only two arguments (i.e., is parameter free), then the equivalence hierarchy collapses to the one depicted below, where the local system versions coincide with (and, hence, are incorporated into) the global versions.*

Proof: The statement follows directly from Propositions 685 and 690. ■

For a systemic π -institution with a parameter free set of natural transformations, there is only one equivalence property, since all versions of symmetry and all versions of transitivity collapse to a single property.

We provide some examples to show that the implications of Proposition 694 are not equivalences in general, i.e., that the nine classes of the equivalence hierarchy are all distinct.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the LSLF equivalence, but not the LFGB equivalence in $\mathcal{I}$.

Example 696 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = i_\Sigma$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

σ_Σ^b	0	1	2
0	2	1	1
1	0	2	0
2	0	1	2

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are four theory families, but only $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the LSLF equivalence in $\mathcal{I}$, but it does not have the LFGB equivalence in $\mathcal{I}$.

Note, first, that reflexivity is obvious, since, by definition $\sigma_\Sigma^b(x, x) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $x \in \mathbf{SEN}^b(\Sigma)$. Local system symmetry is also obvious, since the only theory systems in $\mathcal{I}$ are $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$. Local family transitivity is a little more challenging to verify, but it suffices to observe that the pairs that are related modulo $T = \{\{0, 2\}\}$ are as shown on the left diagram and the pairs that are related modulo $T' = \{\{1, 2\}\}$ are as on the right diagram. We conclude that I^b has the LSLF equivalence in $\mathcal{I}$.

On the other hand, for $T = \{\{0, 2\}\} \in \text{ThFam}(\mathcal{I})$, we have $\sigma_\Sigma^b(1, 0) = 0 \in T_\Sigma$, but $\sigma_\Sigma^b(0, 1) = 1 \notin T_\Sigma$. Therefore, the implication defining local family symmetry fails for $T = \{\{0, 2\}\}$. So I^b is not locally family symmetric, and, hence, a fortiori, does not have the LFGB equivalence property in $\mathcal{I}$.

We now present an example to show that there is a π -institution $\mathcal{I}$ with a set of natural transformations that has the GBLF equivalence but not the LSGB equivalence in $\mathcal{I}$.

Example 697 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, with $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2, 3\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2, 3\} \rightarrow \{0, 1, 2, 3\}$ given by $0 \mapsto 2$, $1 \mapsto 3$, $2 \mapsto 2$ and $3 \mapsto 3$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting: $\sigma_\Sigma^b : \{0, 1, 2, 3\}^3 \rightarrow \{0, 1, 2, 3\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x, y) = (0, 1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2, 3\}, \{0, 1, 2, 3\}\}.$$

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, both of which are also theory systems. So it is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the GBLF equivalence in $\mathcal{I}$, but it does not have the LSGB equivalence in $\mathcal{I}$.

First, note that $\sigma_\Sigma^b(\phi, \phi, \psi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$. Thus, I^b is reflexive in $\mathcal{I}$. For global symmetry, the case of $T = \mathbf{SEN}^b$ is trivial, whereas, for $T = \text{Thm}(\mathcal{I})$, observe that, for no $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, with $\phi \neq \psi$, is

it the case that $\sigma_\Sigma^b[\phi, \psi] \leq T$. Thus, the defining condition holds trivially for $\text{Thm}(\mathcal{I})$. So I^b has the global symmetry in $\mathcal{I}$. For local family transitivity, the case of $T = \text{SEN}^b$ is also trivial and for $T = \text{Thm}(\mathcal{I})$, the only pair $\langle \phi, \psi \rangle \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, for which $\sigma_\Sigma^b(\phi, \psi, \xi) \subseteq \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, is the pair $(\phi, \psi) = (0, 1)$. So the defining condition holds for $\text{Thm}(\mathcal{I})$ also. Thus I^b has the local family transitivity. We conclude that I^b has the GBLF equivalence in $\mathcal{I}$.

On the other hand, we have $\sigma_\Sigma^b(0, 1, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(1, 0, 0) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$. So the implication defining local system symmetry fails for $\text{Thm}(\mathcal{I})$. Therefore, I^b does not have the local system symmetry in $\mathcal{I}$.

Next, we present an example to show that there is a π -institution $\mathcal{I}$ with a set of natural transformations that has the LFLS equivalence but not the GBLF equivalence in $\mathcal{I}$.

Example 698 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by the following table:

σ_Σ^b	0	1	2
0	2	2	0
1	2	2	1
2	0	1	2

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that $\mathcal{I}$ has three theory families, but only $\text{Thm}(\mathcal{I})$ and SEN^b are theory systems. So $\mathcal{I}$ is not systemic.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the LFLS equivalence in $\mathcal{I}$, but it does not have the GBLF equivalence in $\mathcal{I}$.

First, since $\sigma_\Sigma^b(\phi, \phi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\phi \in \text{SEN}^b(\Sigma)$, I^b is reflexive in $\mathcal{I}$. Next, observe from the table that, for all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \psi) = \sigma_\Sigma^b(\psi, \phi)$. Therefore, a fortiori, for all $T \in \text{ThFam}(\mathcal{I})$, and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, if $\sigma_\Sigma^b(\phi, \psi) \in T_\Sigma$, then $\sigma_\Sigma^b(\psi, \phi) \in T_\Sigma$, showing that I^b has the local family symmetry in $\mathcal{I}$. For the local system transitivity, the defining implication is trivial in the case of SEN^b , whereas in the case of $\text{Thm}(\mathcal{I})$, it is straightforward to check based on the table defining σ_Σ^b . Thus, I^b has indeed the LFLS equivalence in $\mathcal{I}$.

On the other hand, consider the theory family $T = \{\{1, 2\}\}$. We have $\sigma_\Sigma^b(0, 1) = 2$ and $\sigma_\Sigma^b(1, 2) = 1$, i.e., $\sigma_\Sigma^b(0, 1), \sigma_\Sigma^b(1, 2) \in T_\Sigma$, whereas $\sigma_\Sigma^b(0, 2) = 0 \notin T_\Sigma$. Therefore, I^b does not have the local family transitivity and, hence, a fortiori, does not satisfy the GBLF equivalence property in $\mathcal{I}$.

Finally, we present an example to show that there is a π -institution $\mathcal{I}$ with a set of natural transformations that has the LFGB equivalence but not the GBLS equivalence in $\mathcal{I}$.

Example 699 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, with $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2, 3, 4, 5\}$ and $\text{SEN}^b(f) : \{0, 1, 2, 3, 4, 5\} \rightarrow \{0, 1, 2, 3, 4, 5\}$ given by $0 \mapsto 3$, $1 \mapsto 4$, $2 \mapsto 5$, $3 \mapsto 3$, $4 \mapsto 4$ and $5 \mapsto 5$;

- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ defined by letting: $\sigma_\Sigma^b : \{0, 1, 2, 3, 4, 5\}^3 \rightarrow \{0, 1, 2, 3, 4, 5\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 3, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \text{ or } \{x, y\} = \{1, 2\} \\ & \text{or } z = 3 \text{ or } z = 4 \text{ or } z = 5 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{ \{3, 4, 5\}, \{0, 1, 2, 3, 4, 5\} \}.$$

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , both of which are also theory systems. So it is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the LFGB equivalence in $\mathcal{I}$, but it does not have the GBLs equivalence in $\mathcal{I}$.

First, note that $\sigma_\Sigma^b(\phi, \phi, \psi) = 3 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\phi, \psi \in \text{SEN}^b(\Sigma)$. Thus, I^b is reflexive in $\mathcal{I}$. For local family symmetry, the case of $T = \text{SEN}^b$ is trivial, whereas, for $T = \text{Thm}(\mathcal{I})$, observe that, if $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, are such that $\sigma_\Sigma^b(\phi, \psi, \xi) \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, then $\{x, y\} = \{0, 1\}$ or $\{x, y\} = \{1, 2\}$. Thus, I^b is local family symmetric. For global transitivity, the case of $T = \text{SEN}^b$ is also trivial and for $T = \text{Thm}(\mathcal{I})$, there is no pair $\langle \phi, \psi \rangle \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, for which $\sigma_\Sigma^b[\phi, \psi] \subseteq \text{Thm}(\mathcal{I})$. So the defining condition holds trivially for $\text{Thm}(\mathcal{I})$ also. Thus I^b has the global transitivity. We conclude that I^b has the LFGB equivalence in $\mathcal{I}$.

On the other hand, we have $\sigma_\Sigma^b(0, 1, \xi) = 3 \in \text{Thm}_\Sigma(\mathcal{I})$ and $\sigma_\Sigma^b(1, 2, \xi) = 3 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(0, 2, 0) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$. So the implication defining local system transitivity fails for $\text{Thm}(\mathcal{I})$. Therefore, I^b does not have the local system transitivity in $\mathcal{I}$.

We close the study of equivalence by providing, again, a transfer property.

Corollary 700 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has an equivalence property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, I has the corresponding equivalence property in $\mathcal{A}$.*

Proof: This follows directly from Propositions 683, 688 and 693. $\blacksquare$

10.7 Antisymmetry

We look next at the antisymmetry property.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that:

- I^b has the **local antisymmetry** in $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \tilde{\xi}) \subseteq \text{Thm}_\Sigma(\mathcal{I})$ and $I_\Sigma^b(\psi, \phi, \tilde{\xi}) \subseteq \text{Thm}_\Sigma(\mathcal{I})$, for all $\tilde{\xi} \in \mathbf{SEN}^b(\Sigma)$, imply $\phi = \psi$;
- I^b has the **global antisymmetry** in $\mathcal{I}$ if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$ and $I_\Sigma^b[\psi, \phi] \leq \text{Thm}(\mathcal{I})$ imply $\phi = \psi$.

The antisymmetry properties stratify into the following hierarchy.

Proposition 701 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. If I^b has the local antisymmetry in $\mathcal{I}$, then it has the global antisymmetry in $\mathcal{I}$.*

Proof: Suppose that I^b has the local antisymmetry and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $I_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$ and $I_\Sigma^b[\psi, \phi] \leq \text{Thm}(\mathcal{I})$. Then we get, in particular, that, for all $\tilde{\xi} \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \tilde{\xi}) \subseteq \text{Thm}_\Sigma(\mathcal{I})$ and $I_\Sigma^b(\psi, \phi, \tilde{\xi}) \subseteq \text{Thm}_\Sigma(\mathcal{I})$. Thus, by local antisymmetry, we obtain $\phi = \psi$. We conclude that I^b has the global antisymmetry in $\mathcal{I}$. $\blacksquare$

Proposition 701 has established the following hierarchy of antisymmetry properties:

We look, next, at a natural sufficient condition under which the antisymmetry properties coincide.

Proposition 702 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. If I^b has only two arguments (i.e., is parameter free), then the local antisymmetry and the global antisymmetry properties coincide.*

Proof: Suppose that I^b is parameter free and has the global antisymmetry in $\mathcal{I}$. Let $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $I_\Sigma^b(\phi, \psi) \subseteq \text{Thm}_\Sigma(\mathcal{I})$ and $I_\Sigma^b(\psi, \phi) \subseteq \text{Thm}_\Sigma(\mathcal{I})$. Then, by Proposition 99, $I_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$ and $I_\Sigma^b[\psi, \phi] \leq \text{Thm}(\mathcal{I})$. Thus, by global antisymmetry, $\phi = \psi$. Therefore, I^b has the local antisymmetry in $\mathcal{I}$. ■

So in the case of a parameter free set of natural transformations we have a single antisymmetry property.

We provide an example to show that the implication of Proposition 701 is not an equivalence in general. That is, we provide an example of a π -institution $\mathcal{I}$ with a set I^b of natural transformations, with two distinguished arguments, that has the global antisymmetry but not the local antisymmetry in $\mathcal{I}$.

Example 703 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$ and $\mathbf{SEN}^b(f) : \{0, 1\} \rightarrow \{0, 1\}$ given by $0 \mapsto 1$ and $1 \mapsto 1$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^3 \rightarrow \{0, 1\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 0, & \text{if } (x, y, z) = (1, 1, 0) \\ 1, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$. Note that there are two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, both of which are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the global antisymmetry in $\mathcal{I}$, but it does not have the local antisymmetry in $\mathcal{I}$.

To see that I^b has the global antisymmetry in $\mathcal{I}$, it suffices to notice that, for no $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$ is it the case that $I_\Sigma^b[\phi, \psi] \leq \text{Thm}(\Sigma)$. Therefore, the defining condition holds vacuously, for all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$.

On the other hand, for $0 \neq 1$, we have $\sigma_\Sigma^b(0, 1, \xi) = \sigma_\Sigma^b(1, 0, \xi) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \{0, 1\}$. So I^b is not locally antisymmetric in $\mathcal{I}$.

To close the study of antisymmetry properties, we show that they do not transfer from π -institutions to their models. This is to be expected, since the inverse image $\alpha^{-1}(T)$ of the minimum $\mathcal{I}$ filter family of a π -institution $\mathcal{I}$ on an algebraic system $\mathcal{A}$ may not coincide with the theorem system of $\mathcal{I}$.

Example 704 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by $\sigma_\Sigma^b(x, y) = 0$, for all $x, y \in \mathbf{SEN}^b(\Sigma)$.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}.$$

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the local antisymmetry in $\mathcal{I}$, but that there exists an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, such that I does not have the local antisymmetry in $\mathcal{A}$.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be the algebraic system determined as follows:

- **Sign** is the trivial category with a single object A ;
- $\text{SEN} : \mathbf{Sign} \rightarrow \mathbf{Set}$ is specified by $\text{SEN}(A) = \{a, b\}$;
- N is the category of natural transformations generated by the single binary natural transformation $\sigma : \text{SEN}^2 \rightarrow \text{SEN}$ defined by letting $\sigma_A : \{a, b\}^2 \rightarrow \{a, b\}$ be given by $\sigma_A(x, y) = a$, for all $x, y \in \text{SEN}(A)$.

$\mathbf{A}$ is an N^b -algebraic system, as can be seen by sending $\sigma^b \mapsto \sigma$ and extending to categories by composition.

Now let $\langle F, \alpha \rangle : \mathbf{F} \rightarrow \mathbf{A}$ be the morphism defined as follows:

- $F : \mathbf{Sign}^b \rightarrow \mathbf{Sign}$ is the obvious functor between trivial categories;
- $\alpha : \text{SEN}^b \rightarrow \text{SEN} \circ F$ is defined by setting $\alpha_\Sigma(0) = a$, $\alpha_\Sigma(1) = a$ and $\alpha_\Sigma(2) = b$.

Our goal is to show that I^b has the local antisymmetry in $\mathcal{I}$ but that I does not have the local antisymmetry in $\mathcal{A}$. We have, for all $\phi, \psi \in \text{SEN}(\Sigma)$, $\sigma_\Sigma^b(\phi, \psi) \notin \text{Thm}_\Sigma(\mathcal{I})$ and $\sigma_\Sigma^b(\psi, \phi) \notin \text{Thm}_\Sigma(\mathcal{I})$, whence the defining condition of local antisymmetry for I^b is vacuously true. So I^b is locally antisymmetric in $\mathcal{I}$.

On the other hand, note that the least $\mathcal{I}$ -filter system on $\mathcal{A}$ is SEN . Moreover, we have $\sigma_A(a, b) = \sigma_A(b, a) = a \in \text{SEN}(A)$, with $a \neq b$. Thus $I = \{\sigma\}$ does not have the local antisymmetry in $\mathcal{A}$.

10.8 Order

We look next at sets of natural transformations I^b , with two distinguished arguments, that define (modulo theory families) partial order families on the underlying algebraic system of a π -institution $\mathcal{I}$. We assume that I^b has the reflexivity property and study combinations of possible antisymmetry and transitivity properties that the set of connectives may or may not possess.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. Let $X \in \{LC, GB\}$, where LC and GB stand for “LoCal” and “GloBal”, respectively, and let $Y \in \{LF, LS, GB\}$, where LF stands for “Local Family” and LS for “Local System”. We say that I^b has the **XY poset property in $\mathcal{I}$** if it has

- (a) reflexivity in $\mathcal{I}$;
- (b) X antisymmetry in $\mathcal{I}$ and
- (c) Y transitivity in $\mathcal{I}$.

Recall, again, the following hierarchies of antisymmetry and of transitivity properties, which were established in Sections 10.7 and 10.5, respectively:

From these, we can infer the following hierarchy of poset properties.

Corollary 705 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. The six poset properties of I^b satisfy the hierarchy depicted in the accompanying diagram.*

Proof: The statement is a direct consequence of Propositions 701 and 689. ■

Based on the analyses performed on antisymmetry and transitivity, we have the following result regarding natural sufficient conditions under which some of these poset properties coincide.

Corollary 706 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the hierarchy of poset properties collapses to the one depicted on the left of the accompanying diagram;*
- (b) *If I^b has only two arguments (i.e., is parameter free), then the hierarchy of poset properties collapses to the one depicted on the right of the diagram, where, since there is only one antisymmetry property, the qualifications refer to the type of transitivity that holds.*

Proof: The statement follows directly from Propositions 690 and 702. ■

For a systemic π -institution with a parameter free set of natural transformations, there is only one poset property, since the two versions of antisymmetry and all three versions of transitivity collapse, respectively, to a single property.

We provide some examples to show that the implications of Corollary 705 are not equivalences, i.e., the six classes of the poset hierarchy are all distinct in general.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the GBLF poset property, but not the LCGB poset property in $\mathcal{I}$.

Example 707 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2, 3\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2, 3\} \rightarrow \{0, 1, 2, 3\}$ given by $0 \mapsto 2$, $1 \mapsto 3$, $2 \mapsto 2$ and $3 \mapsto 3$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting

$\sigma_\Sigma^b : \{0, 1, 2, 3\}^3 \rightarrow \{0, 1, 2, 3\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x, y) = (0, 1) \text{ or } (x, y) = (1, 0) \\ & \text{or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2, 3\}, \{0, 1, 2, 3\}\}.$$

Note that both theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , are also theory systems. So $\mathcal{I}$ is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the GBLF poset property in $\mathcal{I}$, but it does not have the LCGB poset property in $\mathcal{I}$.

Note, first, that reflexivity is obvious, since, by definition, for all $\phi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$. For global antisymmetry, note that if, for some $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$ and $\sigma_\Sigma^b[\psi, \phi] \leq \text{Thm}(\mathcal{I})$, then we must have $\phi = \psi$. Finally, for local family transitivity, the defining equation holds trivially for $T = \text{SEN}^b$, whereas, if for some $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \chi$, $\sigma_\Sigma^b(\phi, \psi, \xi) \in \{2, 3\}$ and $\sigma_\Sigma^b(\psi, \chi, \xi) \in \{2, 3\}$, for all $\xi \in \text{SEN}^b(\Sigma)$, we must have $\phi = \psi$ or $\psi = \chi$, whence the condition is satisfied in this case as well. Thus, I^b is also locally family transitive in $\mathcal{I}$ and, therefore, has the GBLF poset property in $\mathcal{I}$.

On the other hand, since $\sigma_\Sigma^b(0, 1, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$ and $\sigma_\Sigma^b(1, 0, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, I^b does not have the local antisymmetry property. A fortiori, I^b does not have the LCGB poset property in $\mathcal{I}$.

Next, we present an example to show that there is a π -institution $\mathcal{I}$ with a set of natural transformations that has the LCLS poset property but not the GBLF poset property in $\mathcal{I}$.

Example 708 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, with $f \circ f = i_\Sigma$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 0, & \text{if } (x, y) = (0, 1) \text{ or } (x, y) = (1, 2) \\ 1, & \text{if } (x, y) = (1, 0) \text{ or } (x, y) = (0, 2) \\ 2, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has four theory families, but only $\mathbf{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems. So $\mathcal{I}$ is not systemic.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the LCLS poset property but it does not have the GBLF poset property in $\mathcal{I}$.

First, note that $\sigma_\Sigma^b(\phi, \phi) = 2 \in \mathbf{Thm}_\Sigma(\mathcal{I})$, for all $\phi \in \mathbf{SEN}^b(\Sigma)$. Thus, I^b is reflexive in $\mathcal{I}$. For the local antisymmetry, note that for no $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, with $\phi \neq \psi$ is it the case that both $\sigma_\Sigma^b(\phi, \psi) = \sigma_\Sigma^b(\psi, \phi) = 2$. Finally, for the local system transitivity, the defining condition is trivially satisfied for $\mathbf{SEN}^b$, whereas the pairs related modulo $\mathbf{Thm}(\mathcal{I})$ are as in the following diagram, an examination of which verifies transitivity. Therefore I^b is also locally system transitive in $\mathcal{I}$ and, hence has the LCLS poset property in $\mathcal{I}$.

On the other hand, for $T = \{\{0, 2\}\} \in \mathbf{ThFam}(\mathcal{I})$, we have $\sigma_\Sigma^b(0, 1) = \sigma_\Sigma^b(1, 2) = 0 \in T_\Sigma$, whereas $\sigma_\Sigma^b(0, 2) = 1 \notin T_\Sigma$. So the implication defining local family transitivity fails for T . Therefore, I^b does not have the local family transitivity and, a fortiori, does not have the GBLF poset property in $\mathcal{I}$.

Finally, we look at an example that shows that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the LCGB poset property but not the GBLs poset property in $\mathcal{I}$.

Example 709 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, with $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2, 3, 4, 5\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2, 3, 4, 5\} \rightarrow \{0, 1, 2, 3, 4, 5\}$ given by $0 \mapsto 3$, $1 \mapsto 4$, $2 \mapsto 5$, $3 \mapsto 3$, $4 \mapsto 4$ and $5 \mapsto 5$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2, 3, 4, 5\}^3 \rightarrow \{0, 1, 2, 3, 4, 5\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 3, & \text{if } x = y \text{ or } (x, y) = (0, 1) \text{ or } (x, y) = (1, 2) \\ & \text{or } z = 3 \text{ or } z = 4 \text{ or } z = 5 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{3, 4, 5\}, \{0, 1, 2, 3, 4, 5\}\}.$$

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , both of which are also theory systems. So it is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the LCGB poset property in $\mathcal{I}$, but not the GBLS poset property in $\mathcal{I}$.

First, note that, for all $\phi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi, \xi) = 3 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$. Thus, I^b is reflexive in $\mathcal{I}$. For local antisymmetry, it suffices to observe that, for no $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, is it the case that $\sigma_\Sigma^b(\phi, \psi, \xi) \in \text{Thm}_\Sigma(\mathcal{I})$ and $\sigma_\Sigma^b(\psi, \phi, \xi) \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$. For global transitivity, the defining condition holds trivially for $T = \text{SEN}^b$, whereas for $T = \text{Thm}(\mathcal{I})$, it suffices to note that, for no $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, is it the case that $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$. We conclude that I^b has the LCGB poset property in $\mathcal{I}$.

On the other hand, we have $\sigma_\Sigma^b(0, 1, \xi) = 3 \in \text{Thm}_\Sigma(\mathcal{I})$ and $\sigma_\Sigma^b(1, 2, \xi) = 3 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(0, 2, 0) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$. So the implication defining local system transitivity fails for $\text{Thm}(\mathcal{I})$. Therefore, I^b does not have the local system transitivity in $\mathcal{I}$ and, hence, a fortiori, it does not have the GBLS poset property in $\mathcal{I}$.

Because of the non-transference of antisymmetry, which was shown in Example 704, it is to be expected that none of the poset properties transfers from a π -institution to its models. We provide an example that showcases a π -institution $\mathcal{I}$, with a set I^b of natural transformations having two distinguished arguments, that has the LCLF poset property, but one of whose models does not have the GBGB poset property.

Example 710 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $x, y \in \text{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 1, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}$.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the LCLF poset property in $\mathcal{I}$, but that there exists an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, such that I does not have the GBGB poset property in $\mathcal{A}$.

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be the algebraic system determined as follows:

- **Sign** is the trivial category with a single object A ;
- $\text{SEN} : \mathbf{Sign} \rightarrow \mathbf{Set}$ is specified by $\text{SEN}(A) = \{a, b\}$;
- N is the category of natural transformations generated by the single binary natural transformation $\sigma : \text{SEN}^2 \rightarrow \text{SEN}$ defined by letting $\sigma_A : \{a, b\}^2 \rightarrow \{a, b\}$ be given, for all $x, y \in \text{SEN}(A)$, by

$$\sigma_A(x, y) = a.$$

$\mathbf{A}$ is an N^b -algebraic system, as can be seen by sending $\sigma^b \mapsto \sigma$ and extending to categories by composition.

Now let $\langle F, \alpha \rangle : \mathbf{F} \rightarrow \mathbf{A}$ be the morphism defined as follows:

- $F : \mathbf{Sign}^b \rightarrow \mathbf{Sign}$ is the obvious functor between trivial categories;
- $\alpha : \text{SEN}^b \rightarrow \text{SEN} \circ F$ is defined by setting $\alpha_\Sigma(0) = a$, $\alpha_\Sigma(1) = a$ and $\alpha_\Sigma(2) = b$.

We show that I^b has the LCLF poset property in $\mathcal{I}$ but that I does not have the GBGB poset property in $\mathcal{A}$.

First, since $\sigma_\Sigma^b(\phi, \phi) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$, we have that I^b is reflexive in $\mathcal{I}$. Second, if $\sigma_\Sigma^b(\phi, \psi) = 1 = \sigma_\Sigma^b(\psi, \phi)$, then $\phi = \psi$. So I^b has the local antisymmetry in $\mathcal{I}$. Finally, local family transitivity is obvious, since for no $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$ is it the case that $\sigma_\Sigma^b(\phi, \psi) = 1$. We conclude that I^b has the LCLF poset property in $\mathcal{I}$.

On the other hand, note that the least $\mathcal{I}$ -filter system on $\mathcal{A}$ is SEN and since $\sigma_A(a, b) = \sigma_A(b, a) = a \in \text{SEN}(A)$, with $a \neq b$, $I = \{\sigma\}$ does not have the global antisymmetry in $\mathcal{A}$. So, a fortiori, it does not have the GBGB poset property in $\mathcal{A}$.

10.9 Compatibility

We look next at various versions of the compatibility property, taking again into account both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that:

- I^b has the **local family compatibility in $\mathcal{I}$** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\vec{I}_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^b(\Sigma)$, implies

$$I_{\Sigma'}^b(\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi}), \vec{\xi}) \subseteq T_{\Sigma'},$$

for all $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma')$;

- I^b has the **local system compatibility in $\mathcal{I}$** if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\vec{I}_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^b(\Sigma)$, implies

$$I_{\Sigma'}^b(\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi}), \vec{\xi}) \subseteq T_{\Sigma'},$$

for all $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma')$;

- I^b has the **global family compatibility in $\mathcal{I}$** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\vec{I}_\Sigma^b[\phi, \psi] \leq T$ implies

$$I_{\Sigma'}^b[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi})] \leq T,$$

for all $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi} \in \text{SEN}^b(\Sigma')$;

- I^b has the **global system compatibility** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\vec{I}^b_\Sigma[\phi, \psi] \leq T$ implies

$$I^b_{\Sigma'}[\sigma^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma^b_{\Sigma'}(\text{SEN}^b(f)(\psi), \vec{\chi})] \leq T,$$

for all $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi} \in \text{SEN}^b(\Sigma')$.

The following proposition establishes a hierarchy of compatibility properties.

Proposition 711 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If I^b has the local family compatibility, then it has the local system compatibility in $\mathcal{I}$;*
- (b) *If I^b has the local system compatibility, then it has the global family compatibility in $\mathcal{I}$;*
- (c) *I^b has the global family compatibility in $\mathcal{I}$ if and only if it has the global system compatibility in $\mathcal{I}$.*

Proof: Part (a) and one of the implications in Part (c) follow directly from the fact that every theory system of $\mathcal{I}$ is also a theory family of $\mathcal{I}$.

For Part (b), suppose that I^b has the local system compatibility in $\mathcal{I}$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\vec{I}^b_\Sigma[\phi, \psi] \leq T$. Then, by Lemma 93, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\vec{I}^b_{\Sigma'}[\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi)] \leq T.$$

This implies, by Lemma 99, that, for all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\vec{I}^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), \vec{\xi}) \subseteq \overleftarrow{T}_{\Sigma'}.$$

Since I^b has the local system compatibility and, by Proposition 42, $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, we get that, for all $\sigma^b \in N^b$, all $\Sigma'' \in |\mathbf{Sign}^b|$, all $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

and all $\vec{\chi} \in \text{SEN}^b(\Sigma')$ and $\vec{\xi} \in \text{SEN}^b(\Sigma'')$,

$$\begin{aligned} & I^b_{\Sigma''}(\sigma^b_{\Sigma''}(\text{SEN}^b(gf)(\phi), \text{SEN}^b(g)(\vec{\chi})), \\ & \sigma^b_{\Sigma''}(\text{SEN}^b(gf)(\psi), \text{SEN}^b(g)(\vec{\chi})), \vec{\xi}) \subseteq T_{\Sigma''}, \end{aligned}$$

or, equivalently,

$$\begin{aligned} I_{\Sigma''}^b(\text{SEN}^b(g)(\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi})), \\ \text{SEN}^b(g)(\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi})), \vec{\xi}) \subseteq T_{\Sigma''}. \end{aligned}$$

Since this holds for all $\Sigma'' \in |\mathbf{Sign}^b|$, $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$ and $\vec{\xi} \in \text{SEN}^b(\Sigma'')$, we conclude that $I_{\Sigma'}^b[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi})] \leq T$. Therefore I^b has the global family compatibility in $\mathcal{I}$.

Suppose, finally, that I^b has the global system compatibility in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\vec{I}_{\Sigma}^b[\phi, \psi] \leq T$. By Lemma 99, we get that $\vec{I}_{\Sigma}^b[\phi, \psi] \leq \overleftarrow{T}$. Since I^b has the global system compatibility and, by Proposition 42, $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, we get that, for all $\sigma^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi} \in \text{SEN}^b(\Sigma')$, $I_{\Sigma'}^b[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi})] \leq \overleftarrow{T}$. Using again Lemma 99, we conclude that $I_{\Sigma'}^b[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi})] \leq T$. Therefore, I^b has the global family compatibility in $\mathcal{I}$. ■

Proposition 711 has established the following hierarchy of compatibility properties:

We look, next, at some natural sufficient conditions under which some of these three compatibility properties coincide.

Proposition 712 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the local family and the local system compatibility coincide;*
- (b) *If I^b has only two arguments (i.e., is parameter free), then the local system compatibility and the global compatibility coincide.*

Proof: If $\mathcal{I}$ is systemic, then all theory families are theory systems and, hence, the local family and local system compatibility properties coincide.

Suppose, next that I^b is parameter free and has the global system compatibility in $\mathcal{I}$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that

$\vec{I}^b_\Sigma(\phi, \psi) \subseteq T_\Sigma$. Then, by Proposition 99, $\vec{I}^b_\Sigma[\phi, \psi] \leq T$. Thus, by the global system compatibility, for all $\sigma^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$, $I^b_{\Sigma'}[\sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi})] \leq T$, which implies that, for all $\sigma^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$, $I^b_{\Sigma'}(\sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi})) \subseteq T_{\Sigma'}$. Therefore, I^b has the local system compatibility in $\mathcal{I}$. ■

So in the case of a systemic π -institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas in the case of a parameter free set of natural transformations we have the hierarchy on the right.

Of course, for a systemic π -institution with a parameter free set of natural transformations all four compatibility properties coincide.

We provide some examples to show that the implications of Proposition 711 are not equivalences in general, i.e., in the 3-class hierarchy all inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding compatibility properties are proper inclusions.

We first present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the local system compatibility but not the local family compatibility in $\mathcal{I}$.

Example 713 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by two binary natural transformations:

- $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma^b_\Sigma : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma^b_\Sigma(x, y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 1, & \text{if } \{x, y\} = \{0, 1\} \\ 0, & \text{otherwise} \end{cases} ;$$

- $\lambda^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\lambda^b_\Sigma : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\lambda^b_\Sigma(x, y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 0, & \text{otherwise} \end{cases} .$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and SEN^b are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the local system compatibility in $\mathcal{I}$, but it does not have the local family compatibility in $\mathcal{I}$.

For the local system compatibility note that, if $T = \text{SEN}^b$, then the defining implication is trivially true. If, on the other hand, $T = \text{Thm}(\mathcal{I})$, then $\sigma_\Sigma^b(\phi, \psi) = 2$ if and only if $\phi = 2$ or $\psi = 2$. But then we get, for all $\chi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \sigma_\Sigma^b(\sigma_\Sigma^b(\phi, \chi), \sigma_\Sigma^b(\psi, \chi)) &= 2, \\ \sigma_\Sigma^b(\lambda_\Sigma^b(\phi, \chi), \lambda_\Sigma^b(\psi, \chi)) &= 2. \end{aligned}$$

So I^b has the local system compatibility in $\mathcal{I}$.

To see that I^b does not have the local family compatibility in $\mathcal{I}$, consider the theory family $T = \{\{1, 2\}\}$. We have $\sigma_\Sigma^b(0, 1) = \sigma_\Sigma^b(1, 0) = 1 \in T_\Sigma$, but

$$\sigma_\Sigma^b(\lambda_\Sigma^b(1, 0), \lambda_\Sigma^b(0, 0)) = \sigma_\Sigma^b(0, 0) = 0 \notin T_\Sigma.$$

Therefore, the implication defining local family compatibility fails for $T = \{\{1, 2\}\}$. So I^b does not have the local family compatibility in $\mathcal{I}$.

Next, we present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the global (family) compatibility but not the local system compatibility in $\mathcal{I}$.

Example 714 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with two objects Σ, Σ' and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma'$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1\}$, $\text{SEN}^b(\Sigma') = \{a, b, c\}$ and $\text{SEN}^b(f) : \{0, 1\} \rightarrow \{a, b, c\}$ given by $0 \mapsto b$, $1 \mapsto c$;

- N^b is the category of natural transformations generated by one ternary natural transformation $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$, defined as follows:

– $\sigma_\Sigma^b : \{0, 1\}^3 \rightarrow \{0, 1\}$ is given by

$$\sigma_\Sigma^b(x, y, z) = 0, \text{ for all } x, y, z \in \{0, 1\};$$

– $\sigma_{\Sigma'}^b : \{a, b, c\}^3 \rightarrow \{a, b, c\}$ is given by

$$\sigma_{\Sigma'}^b(x, y, z) = \begin{cases} a, & \text{if } a \in \{x, y, z\} \\ b, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{1\}, \{0, 1\}\}, \quad C_{\Sigma'} = \{\{c\}, \{b, c\}, \{a, b, c\}\}.$$

$\mathcal{I}$ has six theory families all of which, except $\{\{0, 1\}, \{c\}\}$, are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the global family compatibility in $\mathcal{I}$, but it does not have the local system compatibility in $\mathcal{I}$.

For the global compatibility note that, if, for some $x, y \in \text{SEN}^b(\Sigma)$, we have $\sigma_\Sigma^b[x, y] \leq T$, then $T = \text{SEN}^b$. Similarly, if, for some $x, y \in \text{SEN}^b(\Sigma')$, $\sigma_{\Sigma'}^b[x, y] \leq T$, then $T_{\Sigma'} = \{a, b, c\}$. In both cases, the conclusion of the defining implication is trivially true. So I^b has the global compatibility in $\mathcal{I}$.

On the other hand, consider the theory system $T = \{\{0, 1\}, \{b, c\}\}$. Let $\phi = 0$ and $\psi = 1$. Then, we have, for all $z \in \{0, 1\}$,

$$\sigma_\Sigma^b(0, 1, z) = \sigma_\Sigma^b(1, 0, z) = 0 \in T_\Sigma.$$

On the contrary,

$$\sigma_{\Sigma'}^b(\sigma_\Sigma^b(\text{SEN}^b(f))(0), c, c), \sigma_{\Sigma'}^b(\text{SEN}^b(f))(1), c, c), a) = a \notin T_{\Sigma'}.$$

Therefore, the implication defining local system compatibility fails for T . So I^b does not have the local system compatibility in $\mathcal{I}$.

We close by proving that all three compatibility properties transfer from π -institutions to their models.

Proposition 715 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a compatibility property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, I has the corresponding compatibility property in $\mathcal{A}$.*

Proof: If I has a compatibility property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same compatibility property in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I}, \mathcal{F}} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding compatibility in $\mathcal{I}$.

Suppose, conversely, that I^b has a compatibility property in $\mathcal{I}$. We look at each of the three properties in turn.

- (a) Suppose I^b has the local family compatibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, let $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that

$$\vec{I}_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)},$$

for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$. Since this is equivalent to $\alpha_\Sigma(\vec{I}^b_\Sigma(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}$, we get that $\vec{I}^b_\Sigma(\phi, \psi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$. But, by hypothesis, I^b has the local family compatibility in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$. Therefore, we get that, for all $\lambda^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$I^b_{\Sigma'}(\lambda^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \lambda^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi}), \vec{\xi}) \subseteq \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}).$$

This now gives

$$\alpha_{\Sigma'}(I^b_{\Sigma'}(\lambda^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \lambda^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi}), \vec{\xi})) \subseteq T_{F(\Sigma')},$$

or, equivalently,

$$\begin{aligned} I_{F(\Sigma')}(\lambda_{F(\Sigma')}(\mathbf{SEN}(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})), \\ \lambda_{F(\Sigma')}(\mathbf{SEN}(F(f))(\alpha_\Sigma(\psi)), \alpha_{\Sigma'}(\vec{\chi})), \alpha_{\Sigma'}(\vec{\xi})) \subseteq T_{F(\Sigma')}. \end{aligned}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that I has the local family compatibility in $\mathcal{A}$.

- (b) The case of the local system compatibility can be proven similarly, taking into account that, if $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$.

- (c) Suppose that I^b has the global (family) compatibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that

$$\vec{I}_{F(\Sigma)}[\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi)] \leq T.$$

Then, we have, by Lemma 95, $\vec{I}_{\Sigma}^b[\phi, \psi] \leq \alpha^{-1}(T)$. Now, since, by hypothesis, I^b has the global family compatibility in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \mathbf{ThFam}(\mathcal{I})$, we get that, for all $\lambda^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$,

$$I_{\Sigma'}^b[\lambda_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \lambda_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \vec{\chi})] \leq \alpha^{-1}(T),$$

or, equivalently, by Lemma 95,

$$I_{F(\Sigma')}[\alpha_{\Sigma'}(\lambda_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \vec{\chi})), \alpha_{\Sigma'}(\lambda_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \vec{\chi}))] \leq T.$$

But this amounts to

$$I_{F(\Sigma')}[\lambda_{F(\Sigma')}(\mathbf{SEN}(F(f))(\alpha_{\Sigma}(\phi)), \alpha_{\Sigma'}(\vec{\chi})), \lambda_{F(\Sigma')}(\mathbf{SEN}(F(f))(\alpha_{\Sigma}(\psi)), \alpha_{\Sigma'}(\vec{\chi}))] \leq T.$$

Thus, I has the global family compatibility in $\mathcal{A}$. ■

10.10 Congruence

In this section we focus on the three *uniform equivalence properties*, i.e., on LFLF equivalence, LSLS equivalence and GBGB equivalence, and to those we add versions of the compatibility property to obtain several versions of the congruence property.

To fix some terminology, we say that a set I^b of natural transformations in a π -institution $\mathcal{I}$ has:

- the **local family equivalence** in $\mathcal{I}$ if it has the LFLF equivalence in $\mathcal{I}$;
- the **local system equivalence** in $\mathcal{I}$ if it has the LSLS equivalence in $\mathcal{I}$;
- the **global equivalence** in $\mathcal{I}$ if it has the GBGB equivalence in $\mathcal{I}$.

By our work in Section 10.6, we know that these three uniform equivalence properties are stratified in the linear hierarchy shown on the left below.

Moreover, by our study of the compatibility properties in Section 10.9, we know that they also fall into a similar linear hierarchy, as shown in the right diagram.

By combining equivalence with compatibility properties, we obtain nine congruence properties as follows. Let $X, Y \in \{\text{LF}, \text{LS}, \text{GB}\}$, where, as before, LF stands for “Local Family”, LS stands for “Local System” and GB stands for “GloBal”.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that I^b has the **XY-congruence in $\mathcal{I}$** if it has

- the X (uniform) equivalence in $\mathcal{I}$;
- the Y compatibility in $\mathcal{I}$.

Based on the hierarchies of the equivalence and compatibility properties, obtained in Sections 10.6 and 10.9, respectively, we obtain the following hierarchical structure for the various flavors of the congruence property.

Corollary 716 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. The nine congruence properties form the hierarchy shown in the accompanying diagram.*

Proof: This follows directly from Corollary 694 and Proposition 711. ■

Based on the analysis performed on symmetry and transitivity properties in Sections 10.4 and 10.5, respectively, we have the following result regarding natural sufficient conditions under which some of the nine congruence properties above coincide.

Corollary 717 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the congruence hierarchy collapses to the one depicted below, where LC (for LoCal) is used to incorporate the LF and LS properties, which coincide;*

- (b) *If I^b has only two arguments (i.e., is parameter free), then the congruence hierarchy collapses to the one depicted below, where the Local System versions coincide with (and, thus, are incorporated into) the*

GloBal versions.

Proof: The statement follows from Corollary 695 and Proposition 712. ■

For a systemic π -institution with a parameter free set of natural transformations, there is only one congruence property, since all versions of equivalence and all versions of compatibility collapse to a single property.

Instead of studying this entire hierarchy in detail, we refocus, once again, to the *uniformly defined classes*. So we define **LF congruence**, **LS congruence** and **GB congruence** to mean, respectively, LFLF congruence, LSLS congruence and GBGB congruence. These are the three diagonal classes in the original diagram which form, according to Corollary 716, the subhierarchy depicted below.

And, of course, according to Corollary 717, this reduces to the hierarchy depicted on the left below for a systemic π -institution and to the one depicted on the right below for a parameter free set of natural transformations.

We provide examples to show that the three uniform classes of the congruence hierarchy are distinct in general.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the LS congruence, but not the LF congruence property in $\mathcal{I}$.

Example 718 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by a single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 1, & \text{if } (x, y) = (1, 2) \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the local system congruence in $\mathcal{I}$, but it does not have the local family congruence in $\mathcal{I}$.

First note that $\sigma_\Sigma^b(\phi, \phi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\phi \in \{0, 1, 2\}$, whence I^b is reflexive in $\mathcal{I}$. Next note that the condition defining local system symmetry holds trivially for $\mathbf{SEN}^b$, whereas for $\text{Thm}(\mathcal{I})$, if $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$, for some $\phi \neq \psi$, then $\{\phi, \psi\} = \{0, 1\}$, whence $\sigma_\Sigma^b(\psi, \phi) \in \text{Thm}_\Sigma(\mathcal{I})$. So I^b is locally system symmetric in $\mathcal{I}$. For local system transitivity, the defining condition holds, again, trivially for $\mathbf{SEN}^b$, whereas for $\text{Thm}(\mathcal{I})$, it holds due to the fact that $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$ for no $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, with $\phi \neq \psi$, other than $(\phi, \psi) = (0, 1)$ or $(1, 0)$. Thus, I^b is also locally system transitive in

$\mathcal{I}$. Finally, note that the condition defining local system compatibility is also trivial for SEN^b , whereas for $\text{Thm}(\mathcal{I})$, if $\sigma_\Sigma^b(\phi, \psi) = 2$ and $\sigma_\Sigma^b(\psi, \phi) = 2$, with $\phi \neq \psi$, then $\{\phi, \psi\} = \{0, 1\}$ and, in that case,

$$\sigma_\Sigma^b(\sigma_\Sigma^b(\text{SEN}^b(h)(\phi), \chi), \sigma_\Sigma^b(\text{SEN}^b(h)(\psi), \chi)) = 2$$

and

$$\sigma_\Sigma^b(\sigma_\Sigma^b(\chi, \text{SEN}^b(h)(\phi)), \sigma_\Sigma^b(\chi, \text{SEN}^b(h)(\psi))) = 2,$$

for all $h \in \mathbf{Sign}^b(\Sigma, \Sigma)$ and all $\chi \in \{0, 1, 2\}$. Thus, I^b has the local system compatibility in $\mathcal{I}$ and, therefore, has the local system congruence in $\mathcal{I}$.

On the other hand, note that $\sigma_\Sigma^b(1, 2) = 1 \in \{1, 2\}$, but $\sigma_\Sigma^b(2, 1) = 0 \notin \{1, 2\}$. Thus, the defining condition for local family symmetry fails for $T = \{\{1, 2\}\} \in \text{ThFam}(\mathcal{I})$. Hence, I^b is not locally family symmetric in $\mathcal{I}$ and, therefore, a fortiori, it fails to satisfy the local family congruence in $\mathcal{I}$.

Finally, we present an example to show that there is a π -institution $\mathcal{I}$ with a set of natural transformations that has the GB congruence but not the LS congruence in $\mathcal{I}$.

Example 719 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2, 3\}$ and $\text{SEN}^b(f) : \{0, 1, 2, 3\} \rightarrow \{0, 1, 2, 3\}$ given by $0 \mapsto 2$, $1 \mapsto 3$, $2 \mapsto 2$ and $3 \mapsto 3$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2, 3\}^3 \rightarrow \{0, 1, 2, 3\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x, y) = (0, 1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2, 3\}, \{0, 1, 2, 3\}\}.$$

Note that both theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , are also theory systems. So $\mathcal{I}$ is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the GB congruence in $\mathcal{I}$, but it does not have the LS congruence in $\mathcal{I}$.

Note, first, that reflexivity is obvious, since, by definition, for all $\phi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$. For global symmetry, note that if, for some $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$, then we must have $\phi = \psi$, whence $\sigma_\Sigma^b[\psi, \phi] \leq \text{Thm}(\mathcal{I})$ holds. For global transitivity, note again that for no $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, is it the case that $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$, whence the condition is satisfied in this case as well. Finally, the same observation leads to the conclusion that I^b satisfies the global compatibility property in $\mathcal{I}$. We conclude that I^b has the GB congruence in $\mathcal{I}$.

On the other hand, since $\sigma_\Sigma^b(0, 1, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(1, 0, 0) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$, I^b does not have the local system symmetry. A fortiori, I^b does not have the LS congruence in $\mathcal{I}$.

And here is a transfer property for the congruence properties that we have focused on in this section.

Corollary 720 Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a congruence property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \text{Sign}, \text{SEN}, N \rangle$, I has the corresponding congruence property in $\mathcal{A}$.

Proof: This follows directly from Corollary 700 and Proposition 715. ■

10.11 Modus Ponens

We turn now to the study of various versions of the modus ponens property, taking again into account both the duality between local versus global membership and the difference between considering all theory families versus restricting only to theory systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that:

- I^b has the **local family modus ponens (local family MP)** in $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \text{ and, for all } \tilde{\chi} \in \mathbf{SEN}^b(\Sigma), I_\Sigma^b(\phi, \psi, \tilde{\chi}) \subseteq T_\Sigma \text{ imply } \psi \in T_\Sigma;$$

- I^b has the **local system modus ponens (local system MP)** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \text{ and, for all } \tilde{\chi} \in \mathbf{SEN}^b(\Sigma), I_\Sigma^b(\phi, \psi, \tilde{\chi}) \subseteq T_\Sigma \text{ imply } \psi \in T_\Sigma;$$

- I^b has the **global family modus ponens (global family MP)** in $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \text{ and } I_\Sigma^b[\phi, \psi] \leq T \text{ imply } \psi \in T_\Sigma;$$

- I^b has the **global system modus ponens (global system MP)** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \text{ and } I_\Sigma^b[\phi, \psi] \leq T \text{ imply } \psi \in T_\Sigma.$$

The following proposition establishes the hierarchy of modus ponens rules.

Proposition 721 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) *If I^b has the local family MP, then it has both the global family MP in $\mathcal{I}$ and the local system MP in $\mathcal{I}$;*
- (b) *If I^b has the global family MP, then it has the global system MP in $\mathcal{I}$;*
- (c) *If I^b has the local system MP, then it has the global system MP in $\mathcal{I}$.*

Proof:

- (a) Suppose that I^b has the local family MP in $\mathcal{I}$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq T$. Then, we have, in particular, that, for all $\tilde{\chi} \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \tilde{\chi}) \subseteq T_\Sigma$. But then, since $\phi \in T_\Sigma$ and, for all $\tilde{\chi} \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b(\phi, \psi, \tilde{\chi}) \subseteq T_\Sigma$, we get, by the local family MP, that $\psi \in T_\Sigma$. We conclude that I^b has the global family MP in $\mathcal{I}$.

If I^b has the local family MP in $\mathcal{I}$, then it has, a fortiori, the local system MP in $\mathcal{I}$ due to the fact that every theory system of $\mathcal{I}$ is also a theory family.

- (b) This follows, similarly to the second part of (a), from the fact that every theory system of $\mathcal{I}$ is also a theory family.
- (c) We repeat the argument used in the proof of the first part of (a) except reasoning exclusively in terms of theory systems rather than using arbitrary theory families. ■

Proposition 721 has established the following hierarchy of modus ponens properties, where the southwest arrows are based on the family-system duality, whereas the southeast arrows on the local-global duality.

We also note the following regarding natural sufficient conditions under which some of these four classes coincide.

Proposition 722 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the local (global) family MP and the local (global) system MP coincide;*
- (b) *If I^b has only two arguments (i.e., is parameter free), then the local system MP and the global system MP coincide;*
- (c) *If $\mathcal{I}$ is systemic and I^b is parameter free, then the local family MP and the global family MP also coincide.*

Proof:

- (a) If $\mathcal{I}$ is systemic, then all theory families are theory systems and the family and system properties collapse.
- (b) Suppose that I^b is parameter free and that I^b has the global system MP in $\mathcal{I}$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $I_\Sigma^b(\phi, \psi) \subseteq T_\Sigma$. Since T is a theory system, we have, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$I_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi)) = \mathbf{SEN}^b(f)(I_\Sigma^b(\phi, \psi)) \subseteq T_{\Sigma'}.$$

Equivalently, $I_\Sigma^b[\phi, \psi] \leq T$. Thus, by the global system MP, we get that $\psi \in T_\Sigma$. Thus, I^b has the local system MP.

(c) This follows from Parts (a) and (b). ■

So, in the case of a systemic π -institution $\mathcal{I}$, we have the hierarchy pictured on the left, whereas, in the case of a parameter free set of natural transformations, we have the hierarchy on the right.

Finally, for a systemic π -institution with a parameter free set of natural transformations all four MP properties collapse to a single one.

We provide some examples to show that the implications of Proposition 721 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding modus ponens properties are proper inclusions.

We first present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that have the global family MP but not the local system MP in $\mathcal{I}$.

Example 723 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$ and $\mathbf{SEN}^b(f) : \{0, 1\} \rightarrow \{0, 1\}$ given by $0 \mapsto 1$ and $1 \mapsto 1$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^3 \rightarrow \{0, 1\}$ be given by

$$\sigma_\Sigma^b(a, b, c) = \begin{cases} 0, & \text{if } (a, b, c) = (1, 1, 0) \\ 1, & \text{otherwise} \end{cases} .$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments.

Clearly, both $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}$, which are the only theory families, are also theory systems. We show that I^b has the global family MP in $\mathcal{I}$, but it does not have the local system MP in $\mathcal{I}$.

For the global family MP notice that we only need to check the case with $T = \text{Thm}(\mathcal{I})$, $\phi = 1$ and $\psi = 0$. Since $\sigma_\Sigma^b(\text{SEN}^b(f)(1), \text{SEN}^b(f)(0), 0) = \sigma_\Sigma^b(1, 1, 0) = 0$, we have that $I_\Sigma^b[\phi, \psi] \not\leq T$, whence the condition is vacuously satisfied. Therefore, we get that I^b has the global family MP in $\mathcal{I}$.

On the other hand, we have $\sigma_\Sigma^b(1, 0, 0) = \sigma_\Sigma^b(1, 0, 1) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$ and $1 \in \text{Thm}_\Sigma(\mathcal{I})$, but $0 \notin \text{Thm}_\Sigma(\mathcal{I})$, which shows that I^b does not have the local system MP in $\mathcal{I}$.

Next we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that have the local system MP but not the global family MP in $\mathcal{I}$.

Example 724 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = i_\Sigma$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $a, b \in \text{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(a, b) = \begin{cases} 1, & \text{if } (a, b) = (2, 0) \\ 0, & \text{if } (a, b) = (2, 1) \\ 2, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ having two distinguished arguments.

$\mathcal{I}$ has four theory families, $\text{Thm}(\mathcal{I})$, $T = \{\{0, 2\}\}$, $T' = \{\{1, 2\}\}$ and SEN^b , but only two theory systems, $\text{Thm}(\mathcal{I})$ and SEN^b . We show that I^b has the local system MP in $\mathcal{I}$, but it does not have the global family MP in $\mathcal{I}$.

For the local system MP notice that we only need to check the case for $\text{Thm}(\mathcal{I})$, $\phi = 2$ and $\psi = 0$ or $\psi = 1$. Since $\sigma_\Sigma^b(2, 0) = 1 \notin \text{Thm}_\Sigma(\mathcal{I})$ and $\sigma_\Sigma^b(2, 1) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$, we conclude that I^b has the local system MP in $\mathcal{I}$.

On the other hand, for the theory family T and for $\phi = 0$ and $\psi = 1$, we get that $\phi = 0 \in T_\Sigma$ and $\sigma_\Sigma^b(\phi, \psi) = \sigma_\Sigma^b(0, 1) = 2$ and

$$\sigma_\Sigma^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi)) = \sigma_\Sigma^b(1, 0) = 2,$$

whence $\sigma_\Sigma^b[0, 1] \leq T$. But clearly $1 \notin T_\Sigma$. Therefore I^b does not have the global family MP in $\mathcal{I}$.

We prove next a transfer property for modus ponens.

Proposition 725 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a modus ponens property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding modus ponens property in $\mathcal{A}$.

Proof: If I has a modus ponens property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same modus ponens in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I}, \mathcal{F}} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding modus ponens in $\mathcal{I}$.

Suppose, conversely, that I^b has a modus ponens property in $\mathcal{I}$. We look at each of the four properties in turn.

- (a) Suppose I^b has the local family MP in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\tilde{\chi})) \subseteq T_{F(\Sigma)},$$

for all $\vec{\chi} \in \text{SEN}^b(\Sigma)$. Since the latter is equivalent to $\alpha_\Sigma(I_\Sigma^b(\phi, \psi, \vec{\chi})) \subseteq T_{F(\Sigma)}$, we get that $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ and $I_\Sigma^b(\phi, \psi, \vec{\chi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, for all $\vec{\chi} \in \text{SEN}^b(\Sigma)$. But, by hypothesis, I^b has the local family MP in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$. Therefore, we get that $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, or, equivalently, $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. This proves that I has the local family MP in $\mathcal{A}$.

- (b) The case of the local system MP can be proven similarly, taking into account that, if $T \in \text{FiSys}^\mathcal{I}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$.
- (c) Suppose that I^b has the global family MP in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that

$$\alpha_\Sigma(\phi) \quad \text{and} \quad I_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T.$$

Then, we have $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ and, by Lemma 95, $I_\Sigma^b[\phi, \psi] \leq \alpha^{-1}(T)$. Now, since, by hypothesis, I^b has the global family MP in $\mathcal{I}$ and, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get that $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$, or, equivalently, $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Thus, I has the global family MP in $\mathcal{A}$.

- (d) Similar to (c). ■

10.12 Syntactic Protoalgebraicity

In this section we focus on the three *uniform congruence properties*, i.e., on LF congruence, LS congruence and GB congruence, and to those we add versions of the modus ponens property to obtain several versions of the syntactic protoalgebraicity property.

By our work in Section 10.10, we know that the three uniform congruence properties are stratified in the linear hierarchy shown in the left diagram.

Moreover, by our study of the modus ponens properties in Section 10.11, we know that they fall into the hierarchy shown in the right diagram.

By combining congruence with modus ponens properties, we obtain twelve syntactic protoalgebraicity properties as follows. Let $X \in \{\text{LF}, \text{LS}, \text{GB}\}$ and

$Y \in \{LF, LS, GF, GS\}$, where, as before, LF stands for “Local Family”, LS stands for “Local System”, GF stands for “Global Family”, GS stands for “Global System” and GB stands for “GloBal”.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that I^b has the **XY syntactic protoalgebraicity in $\mathcal{I}$ (XY SPA in $\mathcal{I}$)** if it has

- the X congruence in $\mathcal{I}$;
- the Y modus ponens in $\mathcal{I}$.

Based on the hierarchies of the congruence and MP properties, established in Sections 10.10 and 10.11, respectively, we obtain the following hierarchical structure for the various flavors of the syntactic protoalgebraicity property.

Corollary 726 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. The twelve syntactic protoalgebraicity properties form the hierarchy shown in the accompanying diagram.*

Proof: This follows directly from Corollary 716 and Proposition 721. ■

Based on the corresponding analysis performed on congruence properties in Section 10.10 and on modus ponens properties in Section 10.11, we have

the following result regarding natural sufficient conditions under which some of the twelve syntactic protoalgebraicity properties coincide.

Corollary 727 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the syntactic protoalgebraicity hierarchy collapses to the one depicted below;*

- (b) *If I^b has only two arguments (i.e., is parameter free), then the syntactic protoalgebraicity hierarchy collapses to the one depicted below, where the Local System versions of congruence coincide with (and are incorporated into) the global versions and the Local and Global System versions of MP also coincide and are denoted by *SYS*.*

Proof: The statement follows from Corollary 717 and Proposition 722. ■

For a systemic π -institution with a parameter free set of natural transformations, there is only one syntactic protoalgebraicity property, since all versions of congruence and all versions of modus ponens collapse to a single property.

Instead of studying this entire hierarchy in detail, we refocus, once again, on the uniformly defined classes. So we define **LF SPA**, **LS SPA**, **GF SPA** and **GS SPA** to mean, respectively, LFLF syntactic, LSLs syntactic, GBGF

syntactic and GBGS syntactic protoalgebraicity. These classes form, according to the diagram above, based on Corollary 726, the sub hierarchy depicted below.

Moreover, according to Corollary 727, this reduces to the hierarchy depicted on the left below for a systemic π -institution and to the one depicted on the right below for a parameter free set of natural transformations.

We provide examples to show that the four uniform classes of the syntactic protoalgebraicity hierarchy are distinct in general.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the LS syntactic protoalgebraicity, but not the GF syntactic protoalgebraicity in $\mathcal{I}$.

Example 728 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by a single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 1, & \text{if } \{x, y\} = \{1, 2\} \\ 0, & \text{otherwise} \end{cases} .$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and SEN^b are theory systems.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the local system syntactic protoalgebraicity in $\mathcal{I}$, but it does not have the global family syntactic protoalgebraicity in $\mathcal{I}$.

First note that $\sigma_\Sigma^b(\phi, \phi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\phi \in \{0, 1, 2\}$, whence I^b is reflexive in $\mathcal{I}$.

Next, note that the condition defining local system symmetry holds trivially for SEN^b , whereas for $\text{Thm}(\mathcal{I})$, if $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$, for some $\phi \neq \psi$, then $\{\phi, \psi\} = \{0, 1\}$, whence $\sigma_\Sigma^b(\psi, \phi) \in \text{Thm}_\Sigma(\mathcal{I})$. So I^b is local system symmetric in $\mathcal{I}$.

For local system transitivity, the defining condition holds, again, trivially for SEN^b , whereas for $\text{Thm}(\mathcal{I})$, it holds due to the fact that $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$ for no $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, other than $(\phi, \psi) = (0, 1)$ or $(1, 0)$. Thus, I^b is also local system transitive in $\mathcal{I}$.

Next, note that the condition defining local system compatibility is also trivial for SEN^b , whereas for $\text{Thm}(\mathcal{I})$, if $\sigma_\Sigma^b(\phi, \psi) = 2$ and $\sigma_\Sigma^b(\psi, \phi) = 2$, with $\phi \neq \psi$, then $\{\phi, \psi\} = \{0, 1\}$ and, in that case,

$$\sigma_\Sigma^b(\sigma_\Sigma^b(\text{SEN}^b(h)(\phi), \chi), \sigma_\Sigma^b(\text{SEN}^b(h)(\psi), \chi)) = 2$$

and

$$\sigma_\Sigma^b(\sigma_\Sigma^b(\chi, \text{SEN}^b(h)(\phi)), \sigma_\Sigma^b(\chi, \text{SEN}^b(h)(\psi))) = 2,$$

for all $h \in \mathbf{Sign}^b(\Sigma, \Sigma)$ and all $\chi \in \{0, 1, 2\}$. Thus, I^b has the local system compatibility in $\mathcal{I}$ and, therefore, has the local system congruence in $\mathcal{I}$.

To finish up, note that, since the only pairs (ϕ, ψ) , with $\phi \neq \psi$, such that $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$ are $(0, 1)$ and $(1, 0)$ and for neither of these is $\phi \in \text{Thm}_\Sigma(\mathcal{I})$, I^b has the local system modus ponens in $\mathcal{I}$ and, therefore, it has the local system syntactic protoalgebraicity in $\mathcal{I}$ as well.

On the other hand, $1 \in \{1, 2\}$ and $\sigma_\Sigma^b[1, 0] \leq \{\{1, 2\}\}$, but $0 \notin \{1, 2\}$. Therefore, I^b does not have the global family *modus ponens* in $\mathcal{I}$ and, hence, a fortiori, it does not have the global family syntactic protoalgebraicity in $\mathcal{I}$.

Next, we present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the GF syntactic protoalgebraicity but not the LS syntactic protoalgebraicity in $\mathcal{I}$.

Example 729 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2, 3\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2, 3\} \rightarrow \{0, 1, 2, 3\}$ given by $0 \mapsto 2$, $1 \mapsto 3$, $2 \mapsto 2$ and $3 \mapsto 3$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2, 3\}^3 \rightarrow \{0, 1, 2, 3\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x, y) = (0, 1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2, 3\}, \{0, 1, 2, 3\}\}.$$

Note that both theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, are also theory systems. So $\mathcal{I}$ is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the global family syntactic protoalgebraicity in $\mathcal{I}$, but it does not have the local system syntactic protoalgebraicity in $\mathcal{I}$.

Note, first, that reflexivity is obvious, since, by definition, for all $\phi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$. For global symmetry, note that if, for some $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$, then we must have $\phi = \psi$, whence $\sigma_\Sigma^b[\psi, \phi] \leq \text{Thm}(\mathcal{I})$ holds. For global transitivity, note again that for no $\phi, \psi \in \text{SEN}^b(\Sigma)$, with $\phi \neq \psi$, is it the case that $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$, whence the condition is satisfied in this case as well. Finally, the same observation leads to the conclusion that I^b satisfies both the global compatibility property in $\mathcal{I}$ and the global modus ponens. We conclude that I^b has the global family syntactic protoalgebraicity in $\mathcal{I}$.

On the other hand, since $\sigma_\Sigma^b(0, 1, \xi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(1, 0, 0) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$, I^b does not have the local system symmetry. A fortiori, I^b does not have the local system congruence and, hence, does not have the local system syntactic protoalgebraicity in $\mathcal{I}$ either.

And here is a transfer property for the syntactic protoalgebraicity properties that we have focused on in this section.

Corollary 730 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a (uniform) syntactic protoalgebraicity property in $\mathcal{I}$ if and only if, for every algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding syntactic protoalgebraicity property in $\mathcal{A}$.*

Proof: This follows directly from Corollary 720 and Proposition 1477. ■

10.13 Invertibility

We study, next, various versions of the invertibility property, once again based on the local versus global and the theory family versus theory system dualities.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. We say that:

- I^b has the **local family invertibility** in $\mathcal{I}$ if there exists a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with one distinguished argument, such that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \vec{I}_\Sigma^b(\tau_\Sigma^b(\phi, \vec{\chi}), \vec{\xi}) \subseteq T_\Sigma, \quad \text{for all } \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma);$$

- I^b has the **local system invertibility in $\mathcal{I}$** if there exists a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with one distinguished argument, such that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \vec{I}_\Sigma^b(\tau_\Sigma^b(\phi, \vec{\chi}), \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma);$$

- I^b has the **global family invertibility in $\mathcal{I}$** if there exists a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with one distinguished argument, such that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \vec{I}^b[\tau_\Sigma^b[\phi]] \leq T;$$

- I^b has the **global system invertibility in $\mathcal{I}$** if there exists a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with one distinguished argument, such that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \vec{I}^b[\tau_\Sigma^b[\phi]] \leq T.$$

We look at the hierarchy of invertibility properties.

Proposition 731 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- If I^b has the local (global) family invertibility, then it has the local (global) system invertibility in $\mathcal{I}$.*
- If I^b has the local system invertibility, then it has the global system invertibility in $\mathcal{I}$.*

Proof: Since every theory system of $\mathcal{I}$ is a theory family, if I^b has the local (global) family invertibility in $\mathcal{I}$, then it has, a fortiori, the local (global) system invertibility in $\mathcal{I}$, with the same witnessing set τ^b of natural transformations in N^b .

Suppose, next, that I^b has the local system invertibility in $\mathcal{I}$, with witnessing set of natural transformations τ^b , and let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$.

- If $\phi \in T_\Sigma$, then, since $T \in \text{ThSys}(\mathcal{I})$, for all $\Sigma', \Sigma'' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$,

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

$$\text{SEN}^b(g)(\text{SEN}^b(f)(\phi)) \in T_{\Sigma''}.$$

Thus, by the local system invertibility, for all $\vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma'')$,

$$I_{\Sigma''}^b(\tau_{\Sigma''}^b(\text{SEN}^b(g)(\text{SEN}^b(f)(\phi)), \vec{\chi}), \vec{\xi}) \subseteq T_{\Sigma''}.$$

In particular, for all $\vec{\chi} \in \text{SEN}^b(\Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma'')$,

$$I_{\Sigma''}^b(\tau_{\Sigma''}^b(\text{SEN}^b(g)(\text{SEN}^b(f)(\phi)), \text{SEN}^b(g)(\vec{\chi})), \vec{\xi}) \subseteq T_{\Sigma''}.$$

So, we get, for all $\vec{\chi} \in \text{SEN}^b(\Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma'')$,

$$I_{\Sigma''}^b(\text{SEN}^b(g)(\tau_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi})), \vec{\xi}) \subseteq T_{\Sigma''}.$$

Since $\Sigma', \Sigma'' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$, $\vec{\chi} \in \text{SEN}^b(\Sigma')$ and $\vec{\xi} \in \text{SEN}^b(\Sigma'')$ were arbitrary, we conclude that $I^b[\tau_{\Sigma}^b[\phi]] \leq T$.

- Suppose, conversely, that $I^b[\tau_{\Sigma}^b[\phi]] \leq T$. This implies

$$I_{\Sigma}^b(\tau_{\Sigma}^b(\phi, \vec{\chi}), \vec{\xi}) \subseteq T_{\Sigma}, \text{ for all } \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma).$$

Thus, by the local system invertibility, $\phi \in T_{\Sigma}$.

We conclude that $\phi \in T_{\Sigma}$ if and only if $I^b[\tau_{\Sigma}^b[\phi]] \leq T$, whence, I^b has the global system invertibility in $\mathcal{I}$. ■

Proposition 731 has established the following hierarchy of invertibility properties:

The following holds regarding natural sufficient conditions under which some of these properties coincide.

Proposition 732 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the local (global) family invertibility and the local (global) system invertibility properties coincide;*

- (b) If I^b is parameter free, then the local system invertibility and the global system invertibility properties coincide, provided that they are witnessed by a parameter free collection $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b .

Proof: If $\mathcal{I}$ is systemic, then the local (global) system invertibility property coincides with the local (global) family invertibility property because of the fact that every theory family in $\mathcal{I}$ is also a theory system.

Suppose, next, that I^b is parameter free and that I^b has the global system invertibility with a parameter free witnessing set of natural transformations $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$.

- If $\phi \in T_\Sigma$, then, by the global system invertibility, $I^b[\tau_\Sigma^b[\phi]] \leq T$. In particular, $I_\Sigma^b(\tau_\Sigma^b(\phi)) \subseteq T_\Sigma$.
- If, conversely, $I_\Sigma^b(\tau_\Sigma^b(\phi)) \subseteq T_\Sigma$, then, since $T \in \text{ThSys}(\mathcal{I})$, we get that, for all $\Sigma', \Sigma'' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$,

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

$$\text{SEN}^b(g)(\text{SEN}^b(f)(I_\Sigma^b(\tau_\Sigma^b(\phi)))) \subseteq T_{\Sigma''}.$$

This can be rewritten as $I_{\Sigma''}^b(\text{SEN}^b(g)(\tau_{\Sigma'}^b(\text{SEN}^b(f)(\phi)))) \subseteq T_{\Sigma''}$. Hence, $I^b[\tau_\Sigma^b[\phi]] \leq T$. Using the global system invertibility, we now conclude that $\phi \in T_\Sigma$.

Thus, the global system invertibility implies the local system invertibility property and, therefore, the local and global system invertibility properties coincide. $\blacksquare$

So, in the case of a systemic π -institution $\mathcal{I}$, the hierarchy of invertibility properties reduces to the one depicted in the left diagram, whereas in the case of a parameter free set of natural transformations I^b , we get the hierarchy depicted on the right, under the proviso that witnessing collections of natural transformations are also parameter free.

Finally, for a systemic π -institution and a parameter free set of natural transformations, all four invertibility properties coincide, subject to the same hypothesis on witnessing collections of natural transformations.

We provide some examples to show that the implications of Proposition 731 are not equivalences in general, i.e., in the hierarchy shown above all

inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding invertibility properties are proper inclusions.

We first present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the local family invertibility but not the global family invertibility in $\mathcal{I}$.

Example 733 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with two objects Σ and Σ' and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma'$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$, $\mathbf{SEN}^b(\Sigma') = \{a, b, c\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{a, b, c\}$ given by $0 \mapsto a$, $1 \mapsto a$ and $2 \mapsto c$;
- N^b is the trivial category of natural transformations consisting of the projections only.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{c\}, \{b, c\}, \{a, b, c\}\}.$$

Consider the set $I^b = \{p^{2,0}\}$, with $p^{2,0} : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ being the projection binary natural transformation (onto the first coordinate), viewed as having two distinguished arguments.

$\mathcal{I}$ has nine theory families, but only five of those are theory systems. So it is not a systemic π -institution. We show that I^b has the local family invertibility in $\mathcal{I}$, but it does not have the global family invertibility in $\mathcal{I}$.

For the local family invertibility, let $\tau^b \equiv \{\iota \approx \iota\}$, where $\iota : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ is the identity (or unary first coordinate projection) natural transformation. Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\overset{\leftrightarrow}{I}_\Sigma^b(\iota_\Sigma(\phi), \iota_\Sigma(\phi)) \in T_\Sigma \quad \text{iff} \quad \phi \in T_\Sigma.$$

Thus, I^b has the local family invertibility in $\mathcal{I}$.

On the other hand, for $T = \{\{1, 2\}, \{b, c\}\} \in \text{ThFam}(\mathcal{I})$, we have $1 \in T_\Sigma$, but

$$p_{\Sigma'}^{2,0}(\text{SEN}^b(f)(1), \text{SEN}^b(f)(1)) = p_{\Sigma'}^{2,0}(a, a) = a \notin T_{\Sigma'}.$$

Therefore I^b does not have the global family invertibility in $\mathcal{I}$.

Next we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the global family invertibility but not the local system invertibility in $\mathcal{I}$.

Example 734 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 1$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single ternary natural transformation $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^3 \rightarrow \{0, 1, 2\}$ be given, for all $x, y, z \in \text{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 1, & \text{if } x, y \in \{0, 1\} \text{ and } z = 2 \\ 2, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_\Sigma = \{\{2\}, \{0, 1, 2\}\}$. Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , both of which are also theory systems. So $\mathcal{I}$ is systemic. We show that I^b has the global family invertibility in $\mathcal{I}$, but it does not have the local system invertibility in $\mathcal{I}$.

For the global family invertibility, consider $\tau^b = \{\iota \approx \iota\}$, where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ is the identity natural transformation. The case of SEN^b is trivial, whereas for $\text{Thm}(\mathcal{I})$, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi = 2 \quad \text{iff} \quad \vec{I}_{\Sigma}^b[\phi, \phi] \leq \{\{2\}\},$$

which holds, for all $\phi \in \{0, 1, 2\}$, as can be checked on a case-by-case basis.

On the other hand, for the local system invertibility, note that $0 \notin \{2\}$, but $\sigma_{\Sigma}^b(\tau_{\Sigma}(0), \psi) = 2 \in \{2\}$, for every set of unary natural transformations $\tau : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ in N^b . We conclude that I^b does not have the local system invertibility in $\mathcal{I}$.

Finally, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the local system invertibility but not the local family invertibility in $\mathcal{I}$.

Example 735 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_{\Sigma}^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $x, y \in \text{SEN}^b(\Sigma)$, by

$$\sigma_{\Sigma}^b(x, y) = \begin{cases} 2, & \text{if } (x, y) = (2, 2) \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_{\Sigma} = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments.

$\mathcal{I}$ has three theory families, but only $\text{Thm}(\mathcal{I})$, SEN^b are theory systems. So $\mathcal{I}$ is not systemic. We show that I^b has the local system invertibility in $\mathcal{I}$, but it does not have the local family invertibility in $\mathcal{I}$.

For the local system invertibility, consider $\tau^b = \{\iota \approx \iota\}$, where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ is the identity natural transformation. The case of SEN^b is trivial, whereas, for $\text{Thm}(\mathcal{I})$, we have to verify that, for all $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi = 2 \quad \text{iff} \quad \vec{I}_\Sigma^b(\phi, \phi) \subseteq \{\{2\}\}.$$

But this obviously holds, by the definition of I^b .

On the other hand, for the local family invertibility, note that $1 \in \{1, 2\}$, but

$$\sigma_\Sigma^b(\tau_\Sigma(1)) = 0 \notin \{1, 2\},$$

for every set of unary natural transformations $\tau : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ in N^b . We conclude that I^b does not have the local family invertibility in $\mathcal{I}$.

We now prove a transfer property for invertibility.

Proposition 736 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has an invertibility property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding invertibility property in $\mathcal{A}$.

Proof: If I has an invertibility property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same invertibility property in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I}, \mathcal{F}} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding invertibility property in $\mathcal{I}$.

Suppose, conversely, that I^b has an invertibility property in $\mathcal{I}$, with witnessing set of natural transformations $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , having a single distinguished argument. We look at each of the four properties in turn.

- (a) Suppose I^b has the global family invertibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. We then have

$$\begin{aligned} \alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \quad \text{iff} \quad \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \\ & \quad \text{iff} \quad \vec{I}_\Sigma^b[\tau_\Sigma^b[\phi]] \leq \alpha^{-1}(T) \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \alpha(\vec{I}_\Sigma^b[\tau_\Sigma^b[\phi]]) \leq T \\ & \quad \text{iff} \quad \vec{I}[\alpha(\tau_\Sigma^b[\phi])] \leq T \quad (\text{by Lemma 96}) \\ & \quad \text{iff} \quad \vec{I}[\tau_{F(\Sigma)}[\alpha_\Sigma(\phi)]] \leq T. \quad (\text{by Lemma 96}) \end{aligned}$$

Taking, once more, into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that I has the global family invertibility in $\mathcal{A}$.

- (b) The global system invertibility follows analogously, taking into account the fact that if $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$.
- (c) Suppose I^b has the local family invertibility in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned}
\alpha_{\Sigma}(\phi) \in T_{F(\Sigma)} & \text{ iff } \phi \in \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}) \\
& \text{ iff } \vec{I}_{\Sigma}^b(\tau_{\Sigma}^b(\phi, \vec{\chi}), \vec{\xi}) \subseteq \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}), \\
& \quad \text{for all } \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma), \\
& \text{ iff } \alpha_{\Sigma}(\vec{I}_{\Sigma}^b(\tau_{\Sigma}^b(\phi, \vec{\chi}), \vec{\xi})) \subseteq T_{F(\Sigma)}, \\
& \quad \text{for all } \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma), \\
& \text{ iff } \vec{I}_{F(\Sigma)}(\tau_{F(\Sigma)}(\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\vec{\chi})), \alpha_{\Sigma}(\vec{\xi})) \subseteq T_{F(\Sigma)}, \\
& \quad \text{for all } \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma).
\end{aligned}$$

Taking again into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that I has the local family invertibility in $\mathcal{A}$.

- (d) The local system invertibility follows along the same lines, taking again into account the fact that if $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$. ■

10.14 Syntactic Algebraizability

In this section we focus on the four *uniform syntactic protoalgebraicity properties*, i.e., on LF SPA, LS SPA, GF SPA and GS SPA, and we add to those versions of the invertibility property to obtain several versions of the syntactic algebraizability property.

By previous work, we know that the four uniform SPA properties constitute the hierarchy shown on the left below.

Moreover, by our study of invertibility, we know that the various versions of invertibility fall into the hierarchy shown in the right diagram.

By combining syntactic protoalgebraicity with invertibility properties, we obtain sixteen syntactic algebraizability properties as follows. Let $X, Y \in$

$\{LF, LS, GF, GS\}$, where LF stands for “Local Family”, LS stands for “Local System”, GF stands for “Global Family” and GS stands for “Global System”.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that I^b has the **XY syntactic algebraizability in $\mathcal{I}$** (**XY SA in $\mathcal{I}$**) if it has

- the X syntactic protoalgebraicity in $\mathcal{I}$;
- the Y invertibility in $\mathcal{I}$.

Based on the hierarchies of the syntactic protoalgebraicity and invertibility properties, we obtain the following hierarchical structure for the various flavors of the syntactic algebraizability property.

Corollary 737 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. The sixteen syntactic algebraizability properties form the hierarchy shown in the accompanying diagram.*

Proof: This follows directly from Corollary 726 and Proposition 731. ■

Based on the analysis performed on SPA and Invertibility, we have the following result regarding sufficient conditions under which some of the sixteen syntactic algebraizability properties coincide.

Corollary 738 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) If $\mathcal{I}$ is systemic, then the syntactic algebraizability hierarchy collapses to the one depicted below;

- (b) If $I^\flat$ has only two arguments (i.e., is parameter free), then the syntactic algebraizability hierarchy collapses to the one depicted below, where the system versions of both the SPA and the invertibility properties are grouped together under the label *SYS*.

Proof: The statement follows from Corollary 727 and Proposition 732. ■

For a systemic π -institution with a parameter free set of natural transformations, there is only one syntactic protoalgebraicity property, since all versions of syntactic protoalgebraicity and all versions of invertibility collapse to a single property.

Instead of studying this entire hierarchy in detail, we refocus, once again, on the uniformly defined classes. So we define **LF SA**, **LS SA**, **GF SA** and **GS SA** to mean, respectively, LFLF syntactic, LSLS syntactic, GFGF syntactic and GSGS syntactic algebraizability. These classes form the subhierarchy depicted below.

Moreover, according to Corollary 738, this reduces to the hierarchy depicted in the left diagram for a systemic π -institution and to the one depicted on the right for a parameter free set of natural transformations.

We provide examples to show that the inclusions between the four uniform classes of the syntactic algebraizability hierarchy are proper in general.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the LS syntactic algebraizability, but not the LF syntactic algebraizability in $\mathcal{I}$.

Example 739 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by
 - a unary natural transformation $\lambda^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\lambda_\Sigma^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given by $\lambda_\Sigma^b(x) = 2$, for all $x \in \{0, 1, 2\}$;
 - a binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 1, & \text{if } \{x, y\} = \{1, 2\} \\ 0, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems. So $\mathcal{I}$ is not systemic.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the local system syntactic algebraizability in $\mathcal{I}$, but it does not have the local family syntactic algebraizability in $\mathcal{I}$.

First, we look at local system equivalence. The defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for SEN^b . For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that the elements of $\text{SEN}^b(\Sigma)$ are related in local system equivalence modulo $\text{Thm}(\mathcal{I})$ as shown in the diagram. Therefore, I^b has the local system equivalence in $\mathcal{I}$.

Next, observe that, for all $\phi \in \text{SEN}^b(\Sigma)$, the pairs $(\sigma_\Sigma^b(\phi, 0), \sigma_\Sigma^b(\phi, 1))$, $(\sigma_\Sigma^b(0, \phi), \sigma_\Sigma^b(1, \phi))$ and $(\lambda_\Sigma^b(0), \lambda_\Sigma^b(1))$ are related via I^b modulo $\text{Thm}(\mathcal{I})$. Thus, I^b has the local system congruence in $\mathcal{I}$.

Next, note that, since the only pairs (ϕ, ψ) , with $\phi \neq \psi$, such that $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$ are $(0, 1)$ and $(1, 0)$ and for neither of these is $\phi \in \text{Thm}_\Sigma(\mathcal{I})$, I^b has the local system modus ponens in $\mathcal{I}$.

Finally, consider the set $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , given by $\tau^b = \{\iota \approx \lambda^b\}$, where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ is the identity natural transformation. Since, for every $\phi \in \text{SEN}^b(\Sigma)$, we have

$$\phi \in \text{Thm}_\Sigma(\mathcal{I}) \quad \text{iff} \quad \vec{I}_\Sigma(\phi, \lambda_\Sigma^b(\phi)) \subseteq \text{Thm}_\Sigma(\mathcal{I}),$$

we also get that I^b has the local system invertibility in $\mathcal{I}$ and, therefore, we conclude that I^b has the local system algebraizability in $\mathcal{I}$.

On the other hand, $1 \in \{1, 2\}$ and $\sigma_\Sigma^b(1, 0) = 2 \in \{1, 2\}$, but $0 \notin \{1, 2\}$. Therefore, I^b does not have the local family modus ponens in $\mathcal{I}$ and, hence, a fortiori, it does not have the local family syntactic algebraizability in $\mathcal{I}$.

Next, we present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the GS syntactic algebraizability but not the GF syntactic algebraizability in $\mathcal{I}$.

Example 740 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = i_\Sigma$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by
 - a unary natural transformation $\lambda^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\lambda_\Sigma^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given by $\lambda_\Sigma^b(x) = 2$, for all $x \in \{0, 1, 2\}$;
 - a single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 1, & \text{if } \{x, y\} = \{0, 2\} \\ 0, & \text{if } \{x, y\} = \{1, 2\} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has four theory families $\text{Thm}(\mathcal{I})$, $T = \{\{0, 2\}\}$, $T' = \{\{1, 2\}\}$ and $\mathbf{SEN}^b$, but only two theory systems $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$. In particular, $\mathcal{I}$ is not systemic.

Consider the set $I^b = \{\sigma^b\}$, with σ^b having both arguments distinguished. We show that I^b has the global system syntactic algebraizability in $\mathcal{I}$, but it does not have the global family syntactic algebraizability in $\mathcal{I}$.

First, we look at global system equivalence. The defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for $\mathbf{SEN}^b$. For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that the elements of $\mathbf{SEN}^b(\Sigma)$ are related in global system equivalence modulo $\text{Thm}(\mathcal{I})$ as shown in the diagram. Therefore, I^b has the global system equivalence in $\mathcal{I}$.

Next, observe that, for all $\phi \in \text{SEN}^b(\Sigma)$, the pairs $(\sigma_\Sigma^b(\phi, 0), \sigma_\Sigma^b(\phi, 1))$, $(\sigma_\Sigma^b(0, \phi), \sigma_\Sigma^b(1, \phi))$ and $(\lambda_\Sigma^b(0), \lambda_\Sigma^b(1))$ are related via I^b modulo $\text{Thm}(\mathcal{I})$. Thus, I^b has the global system congruence in $\mathcal{I}$.

Next, note that, since the only pairs (ϕ, ψ) , with $\phi \neq \psi$, such that $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$ are $(0, 1)$ and $(1, 0)$ and for neither of these is $\phi \in \text{Thm}_\Sigma(\mathcal{I})$, I^b has the global system *modus ponens* in $\mathcal{I}$.

Finally, consider the set $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , given by $\tau^b = \{\iota \approx \lambda^b\}$, where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ is the identity natural transformation. Since, for every $\phi \in \text{SEN}^b(\Sigma)$, we have

$$\phi \in \text{Thm}_\Sigma(\mathcal{I}) \quad \text{iff} \quad \vec{I}_\Sigma[\phi, \lambda_\Sigma^b(\phi)] \leq \text{Thm}(\mathcal{I}),$$

we also get that I^b has the global system *invertibility* in $\mathcal{I}$ and, therefore, we conclude that I^b has the global system *algebraizability* in $\mathcal{I}$.

On the other hand, $1 \in \{1, 2\}$ and $\sigma_\Sigma^b[1, 0] \leq \{\{1, 2\}\}$, but $0 \notin \{1, 2\}$. Therefore, I^b does not have the global family *modus ponens* in $\mathcal{I}$ and, hence, *a fortiori*, it does not have the global family *syntactic algebraizability* in $\mathcal{I}$.

Note that the preceding example also shows that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the GS syntactic algebraizability but not the LF syntactic algebraizability in $\mathcal{I}$. We present also an additional example depicting a π -institution $\mathcal{I}$ with a set of natural transformations I^b , with two distinguished arguments, that has the GS syntactic algebraizability but not the LS syntactic algebraizability in $\mathcal{I}$.

Example 741 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2, 3\}$ and $\text{SEN}^b(f) : \{0, 1, 2, 3\} \rightarrow \{0, 1, 2, 3\}$ given by $0 \mapsto 2$, $1 \mapsto 3$, $2 \mapsto 2$ and $3 \mapsto 3$;
- N^b is the category of natural transformations generated by

- a unary natural transformation $\lambda^b : \text{SEN}^b \rightarrow \text{SEN}^b$ defined by letting $\lambda_\Sigma^b : \{0, 1, 2, 3\} \rightarrow \{0, 1, 2, 3\}$ be given by $0 \mapsto 2$, $1 \mapsto 3$, $2 \mapsto 2$ and $3 \mapsto 3$;
- a ternary natural transformation $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2, 3\}^3 \rightarrow \{0, 1, 2, 3\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 2, & \text{if } x = y \text{ or } (x, y) = (0, 1) \text{ or } z = 2 \text{ or } z = 3 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2, 3\}, \{0, 1, 2, 3\}\}.$$

Note that both theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , are also theory systems. So $\mathcal{I}$ is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the global (family or system) syntactic algebraizability in $\mathcal{I}$, but it does not have the local (family or system) syntactic algebraizability in $\mathcal{I}$.

Concerning global equivalence, the defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for SEN^b . For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that the relation of global equivalence modulo $\text{Thm}(\mathcal{I})$ is the identity relation. Therefore, I^b has the global system equivalence in $\mathcal{I}$. Because of that, the global compatibility and the global modus ponens are trivially satisfied.

Finally, consider the set $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , given by $\tau^b = \{\iota \approx \lambda^b\}$, where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ is the identity natural transformation. Since, for every $\phi \in \text{SEN}^b(\Sigma)$, we have

$$\phi \in \text{Thm}_\Sigma(\mathcal{I}) \quad \text{iff} \quad \vec{I}_\Sigma[\phi, \lambda_\Sigma^b(\phi)] \leq \text{Thm}(\mathcal{I}),$$

we also get that I^b has the global system invertibility in $\mathcal{I}$ and, therefore, we conclude that I^b has the global system algebraizability in $\mathcal{I}$.

On the other hand, $\sigma_\Sigma^b(0, 1, \xi) \in \text{Thm}_\Sigma(\mathcal{I})$, for all $\xi \in \text{SEN}^b(\Sigma)$, but $\sigma_\Sigma^b(1, 0, 0) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$, whence I^b does not have the local symmetry in $\mathcal{I}$ and, therefore, a fortiori, fails to satisfy the local syntactic algebraizability in $\mathcal{I}$.

We close with a transfer property for the syntactic algebraizability properties that we have focused on in this section.

Corollary 742 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a (uniform) syntactic algebraizability property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding syntactic algebraizability property in $\mathcal{A}$.*

Proof: This follows directly from Corollary 730 and Proposition 736. ■

10.15 Regularity

We turn now to the study of various versions of the regularity property, based on the local versus global and the theory family versus theory system dualities.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. We say that:

- I^b has the **local family regularity** in $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \text{ imply } I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \text{SEN}^b(\Sigma);$$

- I^b has the **local system regularity** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \text{ imply } I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \text{SEN}^b(\Sigma);$$

- I^b has the **global family regularity** in $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \text{ imply } I_\Sigma^b[\phi, \psi] \leq T;$$

- I^b has the **global system regularity** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \text{ imply } I_\Sigma^b[\phi, \psi] \leq T.$$

We give now the hierarchy of regularity properties.

Proposition 743 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) *If I^b has the global family regularity, then it has the local family regularity in $\mathcal{I}$;*
- (b) *If I^b has the local family regularity, then it has the local system regularity in $\mathcal{I}$;*
- (c) *I^b has the global system regularity if and only if it has the local system regularity in $\mathcal{I}$.*

Proof:

- (a) Suppose that I^b has the global family regularity in $\mathcal{I}$. Consider $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, we have, by hypothesis, $I_\Sigma^b[\phi, \psi] \leq T$. But this implies that $I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma)$. Thus, I^b has the local family regularity in $\mathcal{I}$.
- (b) The conclusion follows directly from the fact that every theory system is a theory family of $\mathcal{I}$.
- (c) For the “only if” direction, we repeat the argument used in the proof of Part (a) except reasoning exclusively in terms of theory systems rather than using arbitrary theory families.

Suppose, conversely, that I^b has the local system regularity in $\mathcal{I}$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $T \in \text{ThSys}(\mathcal{I})$, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi) \in T_{\Sigma'}.$$

Thus, by the local system regularity, for all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$I_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Since this holds for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$, we get that $I_\Sigma^b[\phi, \psi] \leq T$. Therefore, I^b has the global system regularity in $\mathcal{I}$. ■

Proposition 743 has established the following hierarchy of regularity properties:

We also note the following regarding natural sufficient conditions under which some of these properties coincide.

Proposition 744 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments. If $\mathcal{I}$ is systemic, then all three regularity properties coincide.*

Proof: If $\mathcal{I}$ is systemic, then the (global) system regularity property coincides with the global family regularity property and this causes the collapsing of the hierarchy. ■

So in the case of a systemic π -institution $\mathcal{I}$, there is only one possible regularity property.

We provide some examples to show that the implications of Proposition 743 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding regularity properties are proper inclusions.

We first present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the local family regularity but not the global family regularity in $\mathcal{I}$.

Example 745 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 1, & \text{if } (x, y) = (1, 1) \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}$.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments.

$\mathcal{I}$ has three theory families, but only $\text{Thm}(\mathcal{I})$ and SEN are theory systems. We show that I^b has the local family regularity in $\mathcal{I}$, but it does not have the global family regularity in $\mathcal{I}$.

For the local family regularity note, first, that $\sigma_{\Sigma}^b(2,2) = 2$, which takes care of $\text{Thm}(\mathcal{I})$ and that the case of SEN^b is trivial. So we only need to check the case with $T = \{\{1,2\}\}$. Since $\sigma_{\Sigma}^b(2,2) = \sigma_{\Sigma}^b(1,2) = \sigma_{\Sigma}^b(2,1) = 2$ and $\sigma_{\Sigma}^b(1,1) = 1$, the defining condition for local family regularity is also satisfied for $T = \{\{1,2\}\}$. Therefore, I^b has the local family regularity in $\mathcal{I}$.

On the other hand, we have $1 \in \{1,2\}$ but $\sigma_{\Sigma}^b(\text{SEN}^b(f)(1), \text{SEN}^b(f)(1)) = \sigma_{\Sigma}^b(0,0) = 0 \notin \{1,2\}$. Thus, $1 \in T$, but $\sigma_{\Sigma}^b[1,1] \not\subseteq T$, which shows that I^b does not have the global family regularity in $\mathcal{I}$.

Next we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the system regularity but not the local family regularity in $\mathcal{I}$.

Example 746 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0,1,2\}$ and $\text{SEN}^b(f) : \{0,1,2\} \rightarrow \{0,1,2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_{\Sigma}^b : \{0,1,2\}^2 \rightarrow \{0,1,2\}$ be given, for all $a, b \in \text{SEN}^b(\Sigma)$, by

$$\sigma_{\Sigma}^b(x, y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 0, & \text{otherwise} \end{cases}$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_{\Sigma} = \{\{2\}, \{1,2\}, \{0,1,2\}\}$. Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments.

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1,2\}\}$ and SEN^b , but only two theory systems $\text{Thm}(\mathcal{I})$ and SEN^b . We show that I^b has the (local) system regularity in $\mathcal{I}$, but it does not have the local family regularity in $\mathcal{I}$.

For the local system regularity note that $\sigma_\Sigma^b(2, 2) = 2$, which takes care of $\text{Thm}(\mathcal{I})$, and that the case of SEN^b is trivial.

On the other hand, for the local family regularity, note that $1 \in T_\Sigma = \{1, 2\}$, but $\sigma_\Sigma^b(1, 1) = 0 \notin T_\Sigma$. Therefore I^b does not have the local family regularity in $\mathcal{I}$.

We now prove a transfer property for regularity.

Proposition 747 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a regularity property in $\mathcal{I}$ if and only if, for every algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding regularity property in $\mathcal{A}$.*

Proof: If I has a regularity property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same regularity property in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^\mathcal{F} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding regularity property in $\mathcal{I}$.

Suppose, conversely, that I^b has a regularity property in $\mathcal{I}$. We look at each of the three properties in turn.

- (a) Suppose I^b has the global family regularity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$ and $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get by global family regularity, $I_\Sigma^b[\phi, \psi] \leq \alpha^{-1}(T)$. Thus, by Lemma 95, $I_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T$. We conclude that I has the global family regularity in $\mathcal{A}$.
- (b) Suppose I^b has the local family regularity in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\phi) \in T_{F(\Sigma)}$ and $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\phi \in \alpha^{-1}(T_{F(\Sigma)})$ and $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get by local family regularity, that

$$I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)}), \text{ for all } \vec{\xi} \in \text{SEN}^b(\Sigma).$$

Thus, $\alpha_\Sigma(I_\Sigma^b(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}$ or, equivalently,

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}, \text{ for all } \vec{\xi} \in \text{SEN}^b(\Sigma).$$

It follows, taking into account the surjectivity of $\langle F, \alpha \rangle$, that I has the local family regularity in $\mathcal{A}$.

- (c) The system regularity follows analogously, taking into account the fact that, if $T \in \text{FiSys}^\mathcal{I}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$. ■

10.16 Syntactic Regularity

In this section we focus on the four uniform syntactic protoalgebraicity properties, LF SPA, LS SPA, GF SPA and GS SPA, and we add to those versions of the regularity property to obtain several versions of the syntactic regularity property.

By previous work, we know that the four uniform SPA properties constitute the hierarchy shown in the left diagram.

Moreover, by our study of regularity, we know that the various versions of regularity fall into the linear hierarchy shown in the right diagram.

By combining syntactic protoalgebraicity with regularity properties, we obtain twelve syntactic regularity properties as follows. Let $X \in \{\text{LF}, \text{LS}, \text{GF}, \text{GS}\}$ and $Y \in \{\text{LF}, \text{GF}, \text{SYS}\}$, where LF stands for “Local Family”, LS stands for “Local System”, GF stands for “Global Family”, GS stands for “Global System” and SYS stands for “SYStem”, abbreviating both the local and the global system properties, in case they are identical.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. We say that I^b has the **XY syntactic regularity in $\mathcal{I}$ (XY SR in $\mathcal{I}$)** if it has

- the X syntactic protoalgebraicity in $\mathcal{I}$;
- the Y regularity in $\mathcal{I}$.

Based on the hierarchies of the syntactic protoalgebraicity and regularity properties, we obtain the following hierarchical structure for the various flavors of the syntactic regularity property.

Corollary 748 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. The twelve syntactic regularity properties form the hierarchy shown in the accompanying diagram.*

Proof: This follows directly from Corollary 726 and Proposition 743. ■

Based on the analysis performed on SPA and regularity, we have the following result regarding sufficient conditions under which some of the twelve syntactic regularity properties coincide.

Corollary 749 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b , with two distinguished arguments.*

- (a) *If $\mathcal{I}$ is systemic, then the syntactic regularity hierarchy collapses to the one depicted below;*

- (b) If $I^\flat$ has only two arguments (i.e., is parameter free), then the syntactic regularity hierarchy collapses to the one depicted below, where the System versions of both the SPA and the invertibility properties are grouped together under the label *SYS*.

Proof: The statement follows from Corollary 727 and Proposition 743. ■

For a systemic π -institution with a parameter free set of natural transformations, there is only one syntactic regularity property, since all versions of syntactic protoalgebraicity and all versions of regularity collapse to a single property.

Instead of studying this entire hierarchy in detail, we concentrate again on the uniformly defined classes. So we define **LF SR**, **LS SR**, **GF SR** and **GS SR** to mean, respectively, LFLF syntactic, LSLF syntactic, GFGF syntactic and GSGS syntactic regularity. These classes form, according to Corollary 748, the sub hierarchy depicted below.

Moreover, according to Corollary 749, this reduces to the hierarchy depicted in the left diagram for a systemic π -institution and to the one depicted in the right diagram for a parameter free set of natural transformations.

We provide examples to show that the inclusions between these four uniform classes of the syntactic regularity hierarchy are proper in general.

First, we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the LS syntactic regularity, but not the LF syntactic regularity in $\mathcal{I}$.

Example 750 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by a binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 1, & \text{if } \{x, y\} = \{1, 2\} \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Note that there are three theory families, but only $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems. So $\mathcal{I}$ is not systemic.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments. We show that I^b has the local system syntactic regularity in $\mathcal{I}$, but it does not have the local family syntactic regularity in $\mathcal{I}$.

First, we look at local system equivalence. The defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for $\mathbf{SEN}^b$. For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that the elements of $\mathbf{SEN}^b(\Sigma)$ are related in local system equivalence modulo $\text{Thm}(\mathcal{I})$ as shown in the diagram. Therefore, I^b has the local system equivalence in $\mathcal{I}$.

Next, observe that, for all $\phi \in \text{SEN}^b(\Sigma)$, the pairs $(\sigma_\Sigma^b(\phi, 0), \sigma_\Sigma^b(\phi, 1))$ and $(\sigma_\Sigma^b(0, \phi), \sigma_\Sigma^b(1, \phi))$ are related via I^b modulo $\text{Thm}(\mathcal{I})$. Thus, I^b has the local system congruence in $\mathcal{I}$.

Next, note that, since the only pairs (ϕ, ψ) , with $\phi \neq \psi$, such that $\sigma_\Sigma^b(\phi, \psi) \in \text{Thm}_\Sigma(\mathcal{I})$ are $(0, 1)$ and $(1, 0)$ and for neither of these is $\phi \in \text{Thm}_\Sigma(\mathcal{I})$, I^b has the local system modus ponens in $\mathcal{I}$.

Finally, for local system regularity, note that the defining condition is trivially satisfied for SEN^b , whereas, for $\text{Thm}(\mathcal{I})$, we clearly have that, if $\phi, \psi \in \text{Thm}_\Sigma(\mathcal{I})$, then $\phi = \psi = 2$, whence $\sigma_\Sigma^b(\phi, \psi) = 2 \in \text{Thm}_\Sigma(\mathcal{I})$. Therefore I^b has the local system regularity in $\mathcal{I}$ and, therefore, we conclude that I^b has the local system syntactic regularity in $\mathcal{I}$.

On the other hand, $1 \in \{1, 2\}$ and $\sigma_\Sigma^b(1, 0) = 2 \in \{1, 2\}$, but $0 \notin \{1, 2\}$. Therefore, I^b does not have the local family modus ponens in $\mathcal{I}$ and, hence, a fortiori, it does not have the local family syntactic regularity in $\mathcal{I}$.

Next, we present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the GS syntactic regularity but not the GF syntactic regularity in $\mathcal{I}$.

Example 751 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = i_\Sigma$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by a single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 1, & \text{if } \{x, y\} = \{0, 2\} \\ 0, & \text{if } \{x, y\} = \{1, 2\} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has four theory families $\text{Thm}(\mathcal{I})$, $T = \{\{0, 2\}\}$, $T' = \{\{1, 2\}\}$ and SEN^b , but only $\text{Thm}(\mathcal{I})$ and SEN^b are theory systems. In particular, $\mathcal{I}$ is not systemic.

Consider the set $I^b = \{\sigma^b\}$, with σ^b having both arguments distinguished. We show that I^b has the global system syntactic regularity in $\mathcal{I}$, but it does not have the global family syntactic regularity in $\mathcal{I}$.

First, we look at global system equivalence. The defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for SEN^b . For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that the elements of $\text{SEN}^b(\Sigma)$ are related in global system equivalence modulo $\text{Thm}(\mathcal{I})$ as shown in the diagram. Therefore, I^b has the global system equivalence in $\mathcal{I}$.

Next, observe that, for all $\phi \in \text{SEN}^b(\Sigma)$, the pairs $(\sigma_\Sigma^b(\phi, 0), \sigma_\Sigma^b(\phi, 1))$ and $(\sigma_\Sigma^b(0, \phi), \sigma_\Sigma^b(1, \phi))$ are related via I^b modulo $\text{Thm}(\mathcal{I})$. Thus, I^b has the global system congruence in $\mathcal{I}$.

Now note that, since the only pairs (ϕ, ψ) , with $\phi \neq \psi$, such that $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$ are $(0, 1)$ and $(1, 0)$ and for neither of these is $\phi \in \text{Thm}_\Sigma(\mathcal{I})$, I^b has the global system modus ponens in $\mathcal{I}$.

For the global system regularity, note that the defining condition is satisfied trivially for SEN^b , whereas for $\text{Thm}(\mathcal{I})$, if $\phi, \psi \in \text{Thm}_\Sigma(\mathcal{I})$, then $\phi, \psi = 2$, whence we get $\sigma_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I})$. Therefore, we conclude that I^b has the global system syntactic regularity in $\mathcal{I}$.

On the other hand, $1 \in \{1, 2\}$ and $\sigma_\Sigma^b[1, 0] \leq \{\{1, 2\}\}$, but $0 \notin \{1, 2\}$. Therefore, I^b does not have the global family modus ponens in $\mathcal{I}$ and, hence, a fortiori, it does not have the global family syntactic regularity in $\mathcal{I}$.

Finally, we present an example of a π -institution $\mathcal{I}$ with a set of natural transformations I^b , with two distinguished arguments, that has the GS syntactic regularity but not the LS syntactic regularity in $\mathcal{I}$.

Example 752 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with a single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2, 3, 4, 5\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2, 3, 4, 5\} \rightarrow \{0, 1, 2, 3, 4, 5\}$ given by $0 \mapsto 0$, $1 \mapsto 1$, $2 \mapsto 4$, $3 \mapsto 5$, $4 \mapsto 4$ and $5 \mapsto 5$;
- N^b is the category of natural transformations generated by a ternary natural transformation $\sigma^b : (\mathbf{SEN}^b)^3 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2, 3, 4, 5\}^3 \rightarrow \{0, 1, 2, 3, 4, 5\}$ be given by

$$\sigma_\Sigma^b(x, y, z) = \begin{cases} 4, & \text{if } x = y \text{ or } \{x, y\} = \{4, 5\} \\ & \text{or } ((x, y) = (1, 4) \text{ and } z = 0, 1, 4, 5) \\ & \text{or } ((x, y) = (1, 5) \text{ and } z = 0, 1, 4, 5) \\ 2, & \text{else if } \{x, y\} \subseteq \{2, 3, 4, 5\} \\ & \text{or } (x, y) = (1, 2) \text{ or } (x, y) = (1, 3) \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{4, 5\}, \{2, 3, 4, 5\}, \{0, 1, 2, 3, 4, 5\}\}.$$

Note that all three theory families, $\text{Thm}(\mathcal{I})$, $T = \{\{2, 3, 4, 5\}\}$ and SEN^b , are also theory systems. So $\mathcal{I}$ is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\text{SEN}^b)^3 \rightarrow \text{SEN}^b$ having two distinguished arguments. We show that I^b has the global (family or system) syntactic regularity in $\mathcal{I}$, but it does not have the local (family or system) syntactic regularity in $\mathcal{I}$.

Concerning global equivalence, the defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for SEN^b . For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that the relation of global equivalence modulo $\text{Thm}(\mathcal{I})$ is the binary relation on $\text{SEN}^b(\Sigma)$ depicted in the left graph in the figure. Moreover, the relation of global equivalence modulo T

is the binary relation on $\text{SEN}^b(\Sigma)$ depicted in the right graph in the figure. Therefore, I^b has the global system equivalence in $\mathcal{I}$.

Looking at these two graphs and taking into account the definition of σ^b , we can see that the defining conditions of the global compatibility and the global modus ponens are also satisfied for all three theory systems.

For global regularity, note again that the defining condition is trivially satisfied for SEN^b , that $\sigma_\Sigma^b[\phi, \psi] \leq \text{Thm}(\mathcal{I})$, if $\phi, \psi \in \{4, 5\}$, and that $\sigma_\Sigma^b[\phi, \psi] \leq T$, if $\phi, \psi \in \{2, 3, 4, 5\}$. Thus, we conclude that I^b has the global regularity in $\mathcal{I}$ and, therefore, I^b has the global system syntactic regularity in $\mathcal{I}$.

On the other hand, $\sigma_\Sigma^b(1, 2, \xi) = 2 \in T_\Sigma$, for all $\xi \in \text{SEN}^b(\Sigma)$, whereas $\sigma_\Sigma^b(2, 1, 0) = 0 \notin T_\Sigma$, whence I^b does not have the local system symmetry in $\mathcal{I}$ and, therefore, a fortiori, fails to satisfy the local system syntactic regularity in $\mathcal{I}$.

We close with a transfer property for the (uniform) syntactic regularity properties that we have studied in this section.

Corollary 753 Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has a (uniform) syntactic regularity property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \text{Sign}, \text{SEN}, N \rangle$, I has the corresponding syntactic regularity property in $\mathcal{A}$.

Proof: This follows directly from Corollary 730 and Proposition 747. ■

10.17 Modus Fortis

We now study versions of modus fortis. This property is better known as the Wójcicki or the Rasiowa property. However, in the next section, we call “Rasiowa property” the combination of syntactic protoalgebraicity with the modus fortis.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. We say that:

- I^b has the **local family modus fortis (local family MF)** in $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\psi \in T_\Sigma \text{ implies } I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathbf{SEN}^b(\Sigma);$$

- I^b has the **local system modus fortis (local system MF)** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\psi \in T_\Sigma \text{ implies } I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma, \text{ for all } \vec{\xi} \in \mathbf{SEN}^b(\Sigma);$$

- I^b has the **global family modus fortis (global family MF)** in $\mathcal{I}$ if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\psi \in T_\Sigma \text{ implies } I_\Sigma^b[\phi, \psi] \leq T;$$

- I^b has the **global system modus fortis (global system MF)** in $\mathcal{I}$ if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\psi \in T_\Sigma \text{ implies } I_\Sigma^b[\phi, \psi] \leq T.$$

We give now the hierarchy of modus fortis properties.

Proposition 754 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.*

- (a) *If I^b has the global family MF, then it has the local family MF in $\mathcal{I}$;*
- (b) *If I^b has the local family MF, then it has the local system MF in $\mathcal{I}$;*
- (c) *I^b has the global system MF if and only if it has the local system MF in $\mathcal{I}$.*

Proof:

- (a) Suppose that I^b has the global family MF in $\mathcal{I}$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\psi \in T_\Sigma$. Then, we have, by hypothesis, $I_\Sigma^b[\phi, \psi] \leq T$. This implies that $I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq T_\Sigma$, for all $\vec{\xi} \in \text{SEN}^b(\Sigma)$. Thus, I^b has the local family MF in $\mathcal{I}$.
- (b) The conclusion follows directly from the fact that every theory system is a theory family of $\mathcal{I}$.
- (c) For the “only if” direction, we repeat the argument used in the proof of Part (a) except reasoning exclusively in terms of theory systems rather than using arbitrary theory families.

Suppose, conversely, that I^b has the local system MF in $\mathcal{I}$. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\psi \in T_\Sigma$. Since $T \in \text{ThSys}(\mathcal{I})$, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, $\text{SEN}^b(f)(\psi) \in T_{\Sigma'}$. Thus, by the local system MF, for all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$I_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Since this holds, for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma')$, we get that $I_\Sigma^b[\phi, \psi] \leq T$. Therefore, I^b has the global system MF in $\mathcal{I}$. ■

Proposition 754 has established the following hierarchy of Modus Fortis properties:

We also note the following regarding natural sufficient conditions under which some of these properties coincide.

Proposition 755 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. If $\mathcal{I}$ is systemic, then all three modus fortis properties coincide.*

Proof: If $\mathcal{I}$ is systemic, then the (global) system modus fortis coincides with the global family modus fortis property and this causes the collapsing of the hierarchy. ■

So in the case of a systemic π -institution $\mathcal{I}$, there is only one possible modus fortis property.

We provide some examples to show that the implications of Proposition 754 are not equivalences in general, i.e., in the hierarchy shown above all inclusions of classes of π -institutions with a set of natural transformations satisfying the corresponding *modus fortis* properties are proper inclusions.

We first present an example to show that there is π -institution $\mathcal{I}$ with a set of natural transformations that has the local family MF but not the global family MF in $\mathcal{I}$.

Example 756 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 1, & \text{if } x \neq 2 \text{ and } y = 1 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Consider the set $I^b = \{\sigma^b\}$, with $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ having two distinguished arguments.

$\mathcal{I}$ has three theory families, but only $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$ are theory systems. We show that I^b has the local family *modus fortis*, but it does not have the global family *modus fortis* in $\mathcal{I}$.

For the local family MF note, first, that, for all $x \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(x, 2) = 2$, which takes care of $\text{Thm}(\mathcal{I})$, and that the case of SEN^b is trivial. So we only need to check the case with $T = \{\{1, 2\}\}$. Since, for all $x \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(x, 2) = 2$ and, also, $\sigma_\Sigma^b(0, 1) = \sigma_\Sigma^b(1, 1) = 1$ and $\sigma_\Sigma^b(2, 1) = 2$, the defining condition for local family MF is also satisfied for $T = \{\{1, 2\}\}$. Therefore, I^b has the local family MF in $\mathcal{I}$.

On the other hand, we have $1 \in \{1, 2\}$ but $\sigma_\Sigma^b(\text{SEN}^b(f)(0), \text{SEN}^b(f)(1)) = \sigma_\Sigma^b(0, 0) = 0 \notin \{1, 2\}$. Thus, $1 \in T$, but $\sigma_\Sigma^b[0, 1] \not\subseteq T$, which shows that I^b does not have the global family MF in $\mathcal{I}$.

Next we present an example to show that there exists a π -institution $\mathcal{I}$, with a set of natural transformations that has the system modus fortis but not the local family modus fortis in $\mathcal{I}$.

Example 757 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $a, b \in \text{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = 2 \text{ or } y = 2 \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$C_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments.

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and SEN^b , but only two theory systems $\text{Thm}(\mathcal{I})$ and SEN^b . We show that I^b has the (local) system MF in $\mathcal{I}$, but it does not have the local family MF in $\mathcal{I}$.

For the local system MF note that, for all $x \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(x, 2) = 2$, which takes care of $\text{Thm}(\mathcal{I})$, and that the case of SEN^b is trivial.

On the other hand, for the local family MF, note that $1 \in T_\Sigma = \{1, 2\}$, but $\sigma_\Sigma^b(0, 1) = 0 \notin T_\Sigma$. Therefore, I^b does not have the local family MF in $\mathcal{I}$.

We finally prove a transfer property for modus fortis.

Proposition 758 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. I^b has an MF property in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, I has the corresponding MF property in $\mathcal{A}$.*

Proof: If I has an MF property in $\mathcal{A}$, for all $\mathcal{A}$, then it has the same property in $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Since $\langle \mathbf{F}, C^{\mathcal{I}, \mathcal{F}} \rangle = \mathcal{I}$, we conclude that I^b has the corresponding MF property in $\mathcal{I}$.

Suppose, conversely, that I^b has an MF property in $\mathcal{I}$. We look at each of the three properties in turn.

- (a) Suppose I^b has the global family MF in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get by global family MF, $I_\Sigma^b[\phi, \psi] \leq \alpha^{-1}(T)$. Thus, by Lemma 95,

$$I_{F(\Sigma)}[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T.$$

We conclude that I has the global family MF in $\mathcal{A}$.

- (b) Suppose I^b has the local family MF in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Since $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get by local family MF, that

$$I_\Sigma^b(\phi, \psi, \vec{\xi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)}), \text{ for all } \vec{\xi} \in \text{SEN}^b(\Sigma).$$

Thus, $\alpha_\Sigma(I_\Sigma^b(\phi, \psi, \vec{\xi})) \subseteq T_{F(\Sigma)}$ or, equivalently,

$$I_{F(\Sigma)}(\alpha_\Sigma(\phi), \alpha_\Sigma(\psi), \alpha_\Sigma(\vec{\xi})) \subseteq T_{F(\Sigma)}, \text{ for all } \vec{\xi} \in \text{SEN}^b(\Sigma).$$

It follows, taking into account the surjectivity of $\langle F, \alpha \rangle$, that I has the local family MF in $\mathcal{A}$.

- (c) The system MF follows analogously, taking into account the fact that if $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, then $\alpha^{-1}(T) \in \text{ThSys}(\mathcal{I})$. ■

10.18 The Rasiowa Property

In this section we focus again on the four uniform syntactic protoalgebraicity properties, LF SPA, LS SPA, GF SPA and GS SPA, and we add to those versions of the modus fortis property to obtain several versions of the Rasiowa property.

By previous work, we know that the four uniform SPA properties constitute the hierarchy shown on the left below.

Moreover, by our study of modus fortis, we know that the various versions of modus fortis (MF) fall into the linear hierarchy shown on the right of the diagram.

By combining syntactic protoalgebraicity with MF properties, we obtain twelve Rasiowa properties as follows. Let $X \in \{LF, LS, GF, GS\}$ and $Y \in \{LF, GF, SYS\}$, where LF stands for “Local Family”, LS stands for “Local System”, GF stands for “Global Family”, GS stands for “Global System” and SYS stands for “SYStem”, abbreviating both the local and the global system properties, when they are identical.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. We say that I^b has the **XY Rasiowa property in $\mathcal{I}$ (XY RW in $\mathcal{I}$)**, or that I^b is **XY Rasiowan in $\mathcal{I}$** , if it has

- the X syntactic protoalgebraicity in $\mathcal{I}$;
- the Y modus fortis in $\mathcal{I}$.

Based on the hierarchies of the syntactic protoalgebraicity and MF properties, we obtain the following a priori hierarchical structure for the various flavors of the Rasiowa property.

Corollary 759 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. The twelve Rasiowa properties form the hierarchy shown on the accompanying diagram.*

Proof: This follows directly from Corollary 726 and Proposition 754. ■

It turns out that all these classes collapse to a single class! Indeed, as we show next, the only π -institutions, with a set of natural transformations having two distinguished arguments, satisfying the global system syntactic protoalgebraicity and the system modus fortis are the inconsistent ones. As a consequence, they also satisfy the local family syntactic protoalgebraicity and the global family modus fortis.

Proposition 760 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. If I^b has the GSSYS Rasiowa property in $\mathcal{I}$, then $\mathcal{I}$ is inconsistent.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$. Since I^b is reflexive, $I_\Sigma^b(\phi, \phi, \vec{\xi}) \subseteq \text{Thm}_\Sigma(\mathcal{I})$, for all $\phi, \vec{\xi} \in \mathbf{SEN}^b(\Sigma)$. Thus, $\text{Thm}_\Sigma(\mathcal{I}) \neq \emptyset$. Fix $t \in \text{Thm}_\Sigma(\mathcal{I})$. Then, for all $\phi \in \mathbf{SEN}^b(\Sigma)$, we get, using the SYS Rasiowa property, $I_\Sigma^b[\phi, t] \leq \text{Thm}(\mathcal{I})$. Then, by GS symmetry, $I_\Sigma^b[t, \phi] \leq \text{Thm}(\mathcal{I})$. Thus, by GS modus ponens, we get $\phi \in \text{Thm}_\Sigma(\mathcal{I})$. Since this holds for all $\phi \in \mathbf{SEN}^b(\Sigma)$, we conclude that $\text{Thm}(\mathcal{I}) = \mathbf{SEN}^b$ and, therefore, $\mathcal{I}$ is inconsistent. ■

So the hierarchy of Corollary 759 consists actually of a single property, which we call the **Rasiowa property**, and the only π -institutions satisfying that property are the inconsistent ones.

The Rasiowa property also transfers.

Corollary 761 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, I^b a collection of natural transformations $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ in N^b , with two*

distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $I^\flat$ has the Rasiowa property in $\mathcal{I}$ if and only if, for every algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, I has the Rasiowa property in $\mathcal{A}$.

Proof: This follows directly from Corollary 730 and Proposition 758. ■

10.19 Modus Fortis and Regularity

Recall the hierarchies of the regularity and modus fortis properties that we have introduced previously. These are depicted again below.

The various versions of these three properties are not independent. In fact the modus fortis properties imply the corresponding regularity properties. We prove these straightforward dependencies in the following two propositions.

Proposition 762 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathbf{SEN}^\flat, N^\flat \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^\flat : (\mathbf{SEN}^\flat)^\omega \rightarrow \mathbf{SEN}^\flat$ a set of natural transformations in $N^\flat$ having two distinguished arguments.*

- (a) *If $I^\flat$ has the global family MF, then it has the global family regularity in $\mathcal{I}$;*
- (b) *If $I^\flat$ has the local family MF, then it has the local family regularity in $\mathcal{I}$;*
- (c) *If $I^\flat$ has the system MF, then it has the system regularity in $\mathcal{I}$.*

Proof: We only provide a proof for Part (a), since Parts (b) and (c) can be proved in essentially the same way. So suppose that $I^\flat$ has the global family modus fortis in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^\flat|$ and $\phi, \psi \in \mathbf{SEN}^\flat(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $\psi \in T_\Sigma$ and $I^\flat$ has the global family modus fortis in $\mathcal{I}$, we get that $I_\Sigma^\flat[\phi, \psi] \leq T$. This shows that $I^\flat$ has the global family regularity in $\mathcal{I}$. ■

Proposition 762, together with the previously established hierarchies of regularity and modus fortis properties, establish the following combined hierarchy of these properties.

Recall, now that, if $\mathcal{I}$ is systemic, all three versions of regularity and modus fortis are identified. Therefore, in the case of a systemic π -institution $\mathcal{I}$ with a set I^b of natural transformations having two distinguished arguments, the hierarchy above reduces to simply

On the other hand, since the property of being parameter free does not affect either the regularity or the modus fortis hierarchies, it has no effect on the mixed hierarchy either.

We present an example of a π -institution $\mathcal{I}$, with a set I^b of natural transformations, having two distinguished arguments, that has the global family regularity property in $\mathcal{I}$, but does not have the system modus fortis property in $\mathcal{I}$.

Example 763 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given, for all $x, y \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 1, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$. Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments.

$\mathcal{I}$ has two theory families $\text{Thm}(\mathcal{I})$ and SEN^b , both of which are theory systems. So it is a systemic π -institution. We show that I^b has the global family regularity in $\mathcal{I}$, but it does not have the system *modus fortis* in $\mathcal{I}$.

For the global family regularity, note that the condition is trivial when $T = \text{SEN}^b$, whereas for $T = \text{Thm}(\mathcal{I})$, if $\phi = \psi = 1 \in \text{Thm}_\Sigma(\mathcal{I})$, we have $\sigma_\Sigma^b(1, 1) = 1$, which gives $\sigma_\Sigma^b[1, 1] \leq \text{Thm}(\mathcal{I})$. Thus, I^b is indeed global family regular in $\mathcal{I}$.

On the other hand, note that $1 \in \text{Thm}_\Sigma(\mathcal{I})$, but $\sigma_\Sigma^b(0, 1) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$. Therefore, I^b does not have the system *MF* in $\mathcal{I}$.

10.20 Regularity and Invertibility

Recall the hierarchies that we have introduced previously based on invertibility and regularity. These are depicted again below.

Connecting the regularity with the invertibility conditions requires additional hypotheses. Namely, we will suppose that the π -institution under consideration has natural theorems and satisfies some form of the *modus ponens* property.

Proposition 764 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, having natural theorems, and $I^b :$*

$(\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments.

- (a) If I^b has the global family modus ponens and the global family regularity, then it has the global family invertibility in $\mathcal{I}$;
- (b) If I^b has the local family modus ponens and the local family regularity, then it has the local family invertibility in $\mathcal{I}$;
- (c) If I^b has the local system modus ponens and the system regularity, then it has the local system invertibility in $\mathcal{I}$;
- (d) If I^b has the global system modus ponens and the system regularity, then it has the global system invertibility in $\mathcal{I}$.

Proof: We only provide a proof for Part (a), since Parts (b)-(d) can be proved in essentially the same way. Let $\tau^b : \text{SEN}^b \rightarrow \text{SEN}^b$ be a natural theorem and suppose that I^b has the global family modus ponens and the global family regularity in $\mathcal{I}$. Consider the singleton $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , given by

$$\tau^b = \{\tau^b \approx \iota\},$$

where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ is the identity natural transformation. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$.

- If $\phi \in T_\Sigma$, then, since $\tau_\Sigma^b(\phi) \in \text{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$, we get, by global family regularity, $I_\Sigma^b[\tau_\Sigma^b(\phi), \phi] \leq T$, i.e., $I_\Sigma^b[\tau_\Sigma^b(\phi)] \leq T$.
- Suppose, conversely, that $I_\Sigma^b[\tau_\Sigma^b(\phi)] \leq T$. Then $I_\Sigma^b[\tau_\Sigma^b(\phi), \phi] \leq T$. Since $\tau_\Sigma^b(\phi) \in T_\Sigma$, we get, by global family modus ponens, $\phi \in T_\Sigma$.

We conclude that $\phi \in T_\Sigma$ if and only if $I_\Sigma^b[\tau_\Sigma^b(\phi)] \leq T$. Thus, I^b has the global family invertibility in $\mathcal{I}$, with witnessing set of natural transformations τ^b .

■

10.21 The Algebraic Hierarchy

Recall the three hierarchies that we have introduced previously based on uniform combinations of the syntactic protoalgebraicity properties and the invertibility, regularity and modus fortis properties. These formed the hierarchies of syntactically algebraizable (SA), syntactically regular (SR) and Rasiowa properties, respectively. The first two are depicted again below, whereas the last consists of a single property, which, as we saw in Proposition 760, is characteristic of inconsistent π -institutions.

The various versions of these three properties are not independent. Since, as was shown in Proposition 762, the modus fortis properties imply the corresponding regularity properties and, as was shown in Proposition 764, regularity properties, fortified with existence of natural theorems and some form of the modus ponens, imply the corresponding invertibility properties, we obtain ensuing relationships between the Rasiowa, syntactic regularity and syntactic algebraizability properties.

Corollary 765 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. If I^b has the Rasiowa property, then it has all four syntactic regularity properties.*

Proof: Directly from the definitions and Proposition 762. ■

Corollary 766 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a set of natural transformations in N^b having two distinguished arguments. If I^b has a syntactic regularity property, then it has the corresponding syntactic algebraizability property in $\mathcal{I}$.*

Proof: We present in detail the reasoning for the global family versions. Suppose that I^b is a set of natural transformations, with two distinguished arguments, having the global family syntactic regularity in $\mathcal{I}$. Note that, by global family syntactic protoalgebraicity, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $I_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I})$. Thus, $\mathcal{I}$ has natural theorems. Moreover, by the definition of global family syntactic regularity, I^b has both the global family modus ponens and the global family regularity in $\mathcal{I}$. It follows now, by Proposition 764, that I^b has the global family invertibility in $\mathcal{I}$. Thus, it also has the global family syntactic algebraizability in $\mathcal{I}$. ■

Corollaries 765 and 766 together with the previously established hierarchies of syntactic algebraizability, syntactic regularity and Rasiowa properties, establish the following combined hierarchy of these properties.

Recall, now that, if $\mathcal{I}$ is systemic, then the two local versions and the two global versions of syntactic algebraizability become identified and that the same holds for syntactic regularity. Therefore, in the case of a systemic π -institution $\mathcal{I}$ with a set I^b of natural transformations having two distinguished arguments, the hierarchy above reduces to the simpler hierarchy shown on the left below.

Furthermore, the property of being parameter free has the effect of collapsing the two versions of system syntactic algebraizability and the two versions of system syntactic regularity properties. Thus, the hierarchy of the three properties for parameter free sets of natural transformations I^b in $\mathcal{I}$ is given by the diagram shown on the right above.

We present some examples to show that all inclusions in the diagram of the hierarchy of Rasiowa, syntactic regularity and syntactic algebraizability properties are proper in general.

We first present an example of a π -institution $\mathcal{I}$, with a set I^b of natural transformations, with two distinguished arguments, that has the local and global family syntactic regularity properties in $\mathcal{I}$, but does not have the Rasiowa property in $\mathcal{I}$.

Example 767 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given, for all $x, y \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 1, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$. $\mathcal{I}$ has two theory families $\mathbf{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, both of which are theory systems. So it is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments. We show that I^b has (all kinds of) the syntactic regularity in $\mathcal{I}$, but it does not have the Rasiowa property in $\mathcal{I}$.

First, we look at the equivalence property. The defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for $\mathbf{SEN}^b$. For the theory system $\mathbf{Thm}(\mathcal{I})$, it suffices to observe that equivalence modulo $\mathbf{Thm}(\mathcal{I})$ coincides with the identity relation on $\mathbf{SEN}^b(\Sigma)$. Therefore, I^b has the local system equivalence in $\mathcal{I}$.

The fact that equivalence modulo $\mathbf{Thm}(\mathcal{I})$ is the identity relation immediately implies that I^b also has the compatibility property and the modus ponens in $\mathcal{I}$.

Finally, for regularity, note that the defining condition is trivially satisfied for $\mathbf{SEN}^b$, whereas, for $\mathbf{Thm}(\mathcal{I})$, we clearly have that, if $\phi, \psi \in \mathbf{Thm}_\Sigma(\mathcal{I})$, then $\phi = \psi = 1$, whence $\sigma_\Sigma^b(\phi, \psi) = 1 \in \mathbf{Thm}_\Sigma(\mathcal{I})$. Therefore I^b has the regularity property in $\mathcal{I}$ and, therefore, we conclude that I^b has the syntactic regularity in $\mathcal{I}$.

On the other hand, since $\mathcal{I}$ is not an inconsistent π -institution, I^b does not have the Rasiowa property in $\mathcal{I}$.

Next, we look at an example of a π -institution $\mathcal{I}$, with a set I^b of natural transformations, with two distinguished arguments, that has the local and global family syntactic algebraizability properties in $\mathcal{I}$, but does not possess the global system syntactic regularity in $\mathcal{I}$.

Example 768 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the category of natural transformations generated by
 - a unary natural transformation $\lambda^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\lambda_\Sigma^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given, for all $x \in \mathbf{SEN}^b(\Sigma)$, by

$$\lambda_\Sigma^b(x) = \begin{cases} 2, & \text{if } x = 2 \\ 1, & \text{otherwise} \end{cases} ;$$

- a binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $x, y \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \\ 0, & \text{if } x \neq y \end{cases} .$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}$. $\mathcal{I}$ has two theory families $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, both of which are theory systems. So it is a systemic π -institution.

Consider the set $I^b = \{\sigma^b\}$, with σ^b having two distinguished arguments. We show that I^b has (all kinds of) the syntactic algebraizability in $\mathcal{I}$, but it does not have (any kind of) the syntactic regularity in $\mathcal{I}$.

First, we look at the equivalence property. The defining conditions for reflexivity, symmetry and transitivity of I^b in $\mathcal{I}$ are all trivially satisfied for SEN^b . For the theory system $\text{Thm}(\mathcal{I})$, it suffices to observe that equivalence modulo $\text{Thm}(\mathcal{I})$ coincides with the identity relation on $\text{SEN}^b(\Sigma)$. Therefore, I^b has the local system equivalence in $\mathcal{I}$.

The fact that equivalence modulo $\text{Thm}(\mathcal{I})$ is the identity relation immediately implies that I^b also has the compatibility property and the modus ponens in $\mathcal{I}$.

Finally, for invertibility, consider the set $\tau : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , defined by $\tau = \{\iota \approx \lambda^b\}$. Note that the defining condition is trivially satisfied for SEN^b , whereas, for $\text{Thm}(\mathcal{I})$, we clearly have that,

$$\phi \in \text{Thm}_\Sigma(\mathcal{I}) \quad \text{iff} \quad \sigma_\Sigma^b(\phi, \lambda_\Sigma^b(\phi)) \in \text{Thm}_\Sigma(\mathcal{I}).$$

Therefore, I^b has the invertibility and, hence, the syntactic algebraizability property in $\mathcal{I}$.

On the other hand, we have $1, 2 \in \text{Thm}_\Sigma(\mathcal{I})$, but $\sigma_\Sigma^b(1, 2) = 0 \notin \text{Thm}_\Sigma(\mathcal{I})$. Therefore, I^b fails to have the regularity property and, hence, a fortiori, does not have the syntactic regularity property in $\mathcal{I}$.

Chapter 11

The Syntactic Leibniz Hierarchy: Foundations

11.1 Introduction

In this chapter, we begin the study of those classes of π -institutions that are defined syntactically. Syntactic definitions, in this sense, involve the existence of a collection of natural transformations satisfying certain properties among those introduced and studied in Chapter 10. More precisely, we look at classes of the syntactic hierarchy that are analogs, and related in certain ways, to those classes near the bottom of the semantic hierarchy, introduced and studied in Chapter 3.

In Section 11.2, we study *syntactic prealgebraicity*. This is the syntactic counterpart of (semantic) prealgebraicity. It is a formalization in the π -institution framework of the property of protoalgebraicity for sentential logics [29] (see, also, [53, 65, 89]). The definition stipulates that for a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, with $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$, to be syntactically prealgebraic it must possess a collection I^b of natural transformations, with two distinguished arguments, satisfying reflexivity, global system transitivity, global system compatibility and global system modus ponens (see Chapter 10, Sections 10.3, 10.5, 10.9 and 10.11, respectively). These properties suffice to ensure that the binary relation system $\overset{\leftrightarrow}{I}^b(T)$ on the sentence functor $\mathbf{SEN}^b$ induced by the symmetrization $\overset{\leftrightarrow}{I}^b$ of I^b and by any theory system T of $\mathcal{I}$ is a congruence system on $\mathbf{F}$, compatible with T , and, in fact, is equal to $\Omega(T)$. The fact that the Leibniz congruence system associated with any theory system of $\mathcal{I}$ is defined, in this way, via the set $\overset{\leftrightarrow}{I}^b$ of natural transformations implies that Ω is monotone on theory systems. Hence, by definition (see Chapter 3, Section 3.3) $\mathcal{I}$ is prealgebraic. On the other hand, the well known equivalence of the two notions when applied to sentential logics is not generally true for arbitrary π -institutions.

To prove a characterization of syntactic prealgebraicity, we introduce a key syntactic concept. Given a π -institution $\mathcal{I}$, we define the *reflexive core* $R^{\mathcal{I}}$ of $\mathcal{I}$ as the collection of all natural transformations, with two distinguished arguments, that define a reflexive relation modulo the theorem system of $\mathcal{I}$ (and, thus, a fortiori, modulo every theory family of $\mathcal{I}$). It turns out that the relation $\overleftarrow{R}^{\mathcal{I}}(T)$ induced by the reflexive core of $\mathcal{I}$ and any theory family T of $\mathcal{I}$ includes the Leibniz congruence system $\Omega(T)$ of T . Moreover, $\overleftarrow{R}^{\mathcal{I}}(T)$ is symmetric and satisfies the compatibility property in $\mathbf{F}$. So among those properties that define syntactic prealgebraicity the one that is of uncertain status for $R^{\mathcal{I}}$ is modus ponens. We show that syntactic prealgebraicity is characterized by $R^{\mathcal{I}}$ having the global system modus ponens in $\mathcal{I}$. Following from this is an alternative characterization. Namely, $\mathcal{I}$ is syntactically prealgebraic if and only if the reflexive core $R^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems of $\mathcal{I}$.

Having provided characterizations of syntactic prealgebraicity, we focus

on pinpointing the exact property that separates (semantic) prealgebraicity from syntactic prealgebraicity. We mentioned that, even though the two properties are identical in the context of sentential logics, syntactic prealgebraicity strictly implies the semantic version for arbitrary π -institutions. So we attempt to find the characteristic difference, i.e., their separating property. Interestingly, this turns out to be a “hybrid” property, straddling syntax and semantics. We consider, again, the reflexive core $R^\mathcal{I}$. For a given signature Σ and arbitrary Σ -sentences ϕ, ψ , we may construct the theory system $C(R_\Sigma^\mathcal{I}[\phi, \psi])$. We say that $R^\mathcal{I}$ is *Leibniz* if, for all Σ and all ϕ, ψ ,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi])).$$

It can be shown that, if the reflexive core possesses the global system modus ponens, then it is Leibniz and that this implication is strict in general. However, if the π -institution is prealgebraic, then the reverse implication also holds. In fact, it is shown that syntactic prealgebraicity is characterized by (semantic) prealgebraicity and having a Leibniz reflexive core.

Section 11.2 closes with a proof of the assertion that syntactic prealgebraicity transfers from a π -institution to every $\mathbf{F}$ -algebraic system. This means, as outlined previously, that if $\mathcal{I}$ is syntactically prealgebraic, with witnessing collection of natural transformations I^b , then, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the π -institution model $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically prealgebraic, with witnessing collection of natural transformations I (corresponding to I^b in $\mathcal{I}$). The property is a consequence of the fact, proven in Chapter 10, that all constituent properties defining syntactic prealgebraicity transfer.

In Section 11.3, we study *syntactic protoalgebraicity*, which is the syntactic analog of protoalgebraicity, studied in Chapter 3, and a stronger version of syntactic prealgebraicity, introduced in Section 11.2. A π -institution $\mathcal{I}$ is syntactically protoalgebraic if there exists a collection I^b of natural transformations in $\mathcal{I}$, with two distinguished arguments, that satisfies reflexivity, global family transitivity, global family compatibility and global family modus ponens. Recall that for syntactic prealgebraicity, the corresponding system versions of these properties are required. Although, on the face of it, this introduces three points of difference in the two definitions, this is not really the case. In Sections 10.5 and 10.9 of Chapter 10, it is shown that global family and global system transitivity are identical properties and the same holds for global family and global system compatibility. Hence, the difference between syntactic protoalgebraicity and syntactic prealgebraicity is limited solely on the version of the modus ponens property required in each case. As was done in Section 11.2 for theory systems, it is shown that the witnessing collection I^b of natural transformations in a syntactically protoalgebraic π -institution $\mathcal{I}$ defines Leibniz congruence systems of theory families, i.e.,

for every theory family T of $\mathcal{I}$, $\overset{\leftarrow}{I}^b(T) = \Omega(T)$, where, once more, $\overset{\leftarrow}{I}^b$ denotes the “symmetrization” of I^b . This property enables one to show that, if $\mathcal{I}$ is

syntactically protoalgebraic, then the Leibniz operator on theory families is monotone and, hence, $\mathcal{I}$ is (semantically) protoalgebraic.

In the second part of the section, the reflexive core $R^{\mathcal{I}}$ of the π -institution $\mathcal{I}$ is used to characterize syntactic protoalgebraicity. It is shown that $\mathcal{I}$ is syntactically protoalgebraic if and only if $R^{\mathcal{I}}$ has the global family modus ponens and, moreover, if that is the case, $R^{\mathcal{I}}$ constitutes a witnessing collection of natural transformations in $\mathcal{I}$ and, as a consequence, defines Leibniz congruence systems of theory families in $\mathcal{I}$. We also use the reflexive core to delineate the boundary between syntactic protoalgebraicity and semantic protoalgebraicity. To this end, we use, again, the property of the reflexive core being Leibniz. In general, if $R^{\mathcal{I}}$ has the global family modus ponens, then it is Leibniz. The reverse implication does not hold in general, but it does hold if the π -institution $\mathcal{I}$ is protoalgebraic. In fact, it is proven that $\mathcal{I}$ is syntactically protoalgebraic if and only if it is protoalgebraic and has a Leibniz reflexive core. Thus, having a Leibniz reflexive core is the characteristic property separating the semantic and syntactic versions of protoalgebraicity. Similarly, and as was the case with the semantic notions, it turns out that the property that separates syntactic protoalgebraicity from syntactic pre-algebraicity is stability, a semantic property that was introduced in Section 3.2 of Chapter 3. Section 11.3 concludes with the assertion that syntactic protoalgebraicity transfers.

Section 11.4 introduces four classes of matrix families that serve as semantics for a given π -institution $\mathcal{I}$. The first is the class $\text{LMatFam}^*(\mathcal{I})$ of all reduced Lindenbaum $\mathcal{I}$ -matrix families. The second is the class $\text{LMatFam}^{\text{Su}}(\mathcal{I})$ of all Suszko reduced Lindenbaum $\mathcal{I}$ -matrix families. The third is the class $\text{MatFam}^*(\mathcal{I})$ of all reduced $\mathcal{I}$ -matrix families and the last one is the class $\text{MatFam}^{\text{Su}}(\mathcal{I})$ of all Suszko reduced $\mathcal{I}$ -matrix families. We say that an arbitrary class $\mathbf{M}$ of matrix families is a *matrix semantics* for a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ if $C = C^{\mathbf{M}}$, that is, if, for all signatures Σ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, we have $\phi \in C_{\Sigma}(\Phi)$ if and only if, for all $\langle \mathcal{A}, T \rangle \in \mathbf{M}$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all signatures Σ' and all signature morphisms $f : \Sigma \rightarrow \Sigma'$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) \in T_{F(\Sigma')}.$$

It is shown that each of the four classes of matrix families introduced above constitutes a matrix semantics for $\mathcal{I}$. The corresponding classes of algebraic system reducts of the matrix models in each of these four matrix family classes are denoted, respectively, by $\text{LAlgSys}^*(\mathcal{I})$, $\text{LAlgSys}^{\text{Su}}(\mathcal{I})$, $\text{AlgSys}^*(\mathcal{I})$ and $\text{AlgSys}^{\text{Su}}(\mathcal{I})$. It is not difficult to see, based on the relevant definitions, that the four classes of matrix models satisfy the inclusions

$$\begin{aligned} \text{LMatFam}^{\text{Su}}(\mathcal{I}) &\subseteq \text{LMatMat}^*(\mathcal{I}), \\ \text{LMatFam}^*(\mathcal{I}) &\subseteq \text{MatFam}^*(\mathcal{I}), \\ \text{MatFam}^*(\mathcal{I}) &\subseteq \text{MatFam}^{\text{Su}}(\mathcal{I}). \end{aligned}$$

These inclusions yield corresponding inclusions between the classes of algebraic system reducts, namely we have also $\text{LAlgSys}^{\text{Su}}(\mathcal{I}) \subseteq \text{LAlgSys}^*(\mathcal{I})$, $\text{LAlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}^*(\mathcal{I})$ and $\text{AlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}^{\text{Su}}(\mathcal{I})$.

In Section 11.5, we study the notion of *algebraic semantics* for a π -institution $\mathcal{I}$ and the closely related notion of *equational definability of truth*. These were among the key concepts of the theory of algebraizable logics of Blok and Pigozzi [36]. They form dual notions to the definability of Leibniz congruence systems, which was studied in Sections 11.2 and 11.3. In the context of algebraizability, the two duals are studied together and they are required to be closely interrelated. On the other hand, in the general theory of algebraic logic, each is studied on its own and has its own role and significance in defining and studying the algebraic hierarchy of logics. In the context of sentential logics, equational definability of truth was pursued by Raftery [78], whereas the definability of the Leibniz congruence forms part of both protoalgebraic [29] and equivalential logics [24, 25] (see, also, [65]).

Given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, a class K of $\mathbf{F}$ -algebraic systems determines a closure family C^K on $\mathbf{F}$. If there exists a collection $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of pairs of natural transformations, with a single distinguished argument, that serves to interpret C into C^K , then K is said to be a τ^b -algebraic semantics for $\mathcal{I}$. Interpretation in this sense means that, for every signature Σ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq C^K(\tau_\Sigma^b[\Phi]).$$

On the other hand, given a class M of $\mathbf{F}$ -matrix families, we say that truth is τ^b -equationally definable in the class if, for every matrix family $\langle \mathcal{A}, T \rangle \in M$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all signatures Σ of $\mathcal{A}$ and all Σ -sentences ϕ ,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^A[\phi] \leq \Delta^A,$$

Δ^A denoting, as usual, the identity relation system on $\mathcal{A}$. Having a τ^b -algebraic semantics and having a matrix (family) semantics in which truth is τ^b -equationally definable are shown to be equivalent. This result goes back to the work of Blok and Pigozzi (see, e.g., Theorem 2.4 of [36]). In Section 11.4, it was shown that the classes

$$\text{LMatFam}^*(\mathcal{I}), \text{LMatFam}^{\text{Su}}(\mathcal{I}), \text{MatFam}^*(\mathcal{I}), \text{MatFam}^{\text{Su}}(\mathcal{I})$$

form matrix semantics for a π -institution $\mathcal{I}$. Moreover, the classes

$$\text{LAlgSys}^*(\mathcal{I}), \text{LAlgSys}^{\text{Su}}(\mathcal{I}), \text{AlgSys}^*(\mathcal{I}), \text{AlgSys}^{\text{Su}}(\mathcal{I}).$$

were defined as the corresponding classes of underlying algebraic systems. Thus, the aforementioned equivalence implies that, should any of the four matrix family classes have truth equationally definable, the corresponding class of algebraic systems would be an algebraic semantics for $\mathcal{I}$.

In Section 11.6, we return to the syntactic hierarchy. We define four a priori different notions of *truth equationality* for a π -institution $\mathcal{I}$. All four involve truth being equationally refinable in one of the four matrix family classes introduced in Section 11.4. For instance, we say that $\mathcal{I}$ is *Leibniz truth equational* if, for some collection τ^b of natural transformations, truth is τ^b -definable in the class $\text{LMatFam}^*(\mathcal{I})$ of Lindenbaum Leibniz reduced matrices of $\mathcal{I}$, in the sense that, for all $\langle \mathcal{F}/\Omega(T), T/\Omega(T) \rangle \in \text{LMatFam}^*(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}.$$

If, instead of $\text{LMatFam}^*(\mathcal{I})$, we take $\text{LMatFam}^{\text{Su}}(\mathcal{I})$, then we obtain *Suszko truth equationality* and, similarly, by considering, respectively, $\text{MatFam}^*(\mathcal{I})$ or $\text{MatFam}^{\text{Su}}(\mathcal{I})$, we obtain *universal Leibniz truth equationality* and *universal Suszko truth equationality*. Of these four truth equationality properties, it turns out that three are equivalent. In fact, Leibniz and universal Leibniz truth equationality and universal Suszko truth equationality turn out to be mutually equivalent. So the truth equationality subhierarchy, as it were, consists of two different classes of which Leibniz truth equationality implies Suszko truth equationality. Finally, based on what was shown in Section 11.5 on the relation between matrix and algebraic semantics, we may conclude that, if a π -institution $\mathcal{I}$ is Leibniz truth equational, all three classes of algebraic systems $\text{LAlgSys}^*(\mathcal{I})$, $\text{AlgSys}^*(\mathcal{I})$ and $\text{AlgSys}^{\text{Su}}(\mathcal{I})$ form algebraic semantics for $\mathcal{I}$.

Section 11.7 is a bridge between Sections 11.6 and 11.8. In Section 11.6, we study versions of truth equationality, a syntactic property of a π -institution. In Section 11.8, we wish to relate truth equationality with complete reflectivity (c-reflectivity), a semantic property, various versions of which were introduced and studied in Chapter 3, Section 3.8. The bridge section establishes some relations between truth equationality and having an algebraic semantics, on the one hand, and gives some characterizations of family c-reflectivity, on the other. We describe briefly this second part.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution. We say that the Suszko operator in $\mathcal{I}$ is *universally family injective* if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and all $\mathcal{I}$ -filter families T and T' on $\mathcal{A}$,

$$\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T') \quad \text{implies} \quad T = T'.$$

Moreover, we say that the Suszko operator has *universal family minimality* if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and every $\mathcal{I}$ -filter family T on $\mathcal{A}$, $T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$ is the least filter family on $\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$. It is shown that universal family injectivity of the Suszko operator is equivalent to universal family minimality. In Section 3.8 of Chapter 3, it is shown that family c-reflectivity transfers, that is, it is equivalent to the property that, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$

and all collections $\mathcal{T} \cup \{T'\}$ of $\mathcal{I}$ -filter families on $\mathcal{A}$,

$$\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$

This property may be termed *universal family c-reflectivity*. We show that it is also equivalent to the assertion that, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and all $\mathcal{I}$ -filter families T, T' on $\mathcal{A}$,

$$\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad \text{implies} \quad T \leq T'.$$

The equivalence of the last two properties allows us to show that family c-reflectivity is equivalent to the universal injectivity of the Suszko operator in $\mathcal{I}$. In summary, the properties of universal family injectivity of the Suszko operator, of universal family minimality of the Suszko operator and of $\mathcal{I}$ being family c-reflective are mutually equivalent properties.

Section 11.8 relates truth equationality with family c-reflectivity. This relation is analogous, and, in a certain sense, dual, to the relation between syntactic protoalgebraicity and (semantic) protoalgebraicity, which was detailed in Section 11.3. A key result, here, is that, if a π -institution $\mathcal{I}$ is truth equational, with witnessing equations τ^b , then the witnessing equations reflect theory families, in the sense that, for every theory family T of $\mathcal{I}$, $\overleftarrow{\tau^b}(\Omega(T)) = T$, where

$$\overleftarrow{\tau^b}_{\Sigma}(\Omega(T)) = \{\phi \in \text{SEN}^b(\Sigma) : \tau^b_{\Sigma}[\phi] \leq \Omega(T)\}.$$

This “reflectivity” property of τ^b allows showing that truth equationality implies family c-reflectivity. The result is the analog of the one asserting that syntactic protoalgebraicity implies protoalgebraicity in the context of Section 11.3. Pursuing the analogy further, we seek a characterization of truth equationality as well as a characteristic property separating truth equationality from family c-reflectivity. The analogous tasks in the context of protoalgebraicity were accomplished using the reflexive core $R^{\mathcal{I}}$ of $\mathcal{I}$. The notion that accomplishes our goals here and that corresponds to the reflexive core is the Suszko core $S^{\mathcal{I}}$ of the π -institution $\mathcal{I}$.

The *Suszko core* $S^{\mathcal{I}}$ of a π -institution $\mathcal{I}$ consists of all natural transformations $\sigma^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, that satisfy, for every theory family T of $\mathcal{I}$,

$$\sigma^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T),$$

i.e., that map a theory family into the Suszko congruence system of the theory family. This defining property turns out to be equivalent to the condition that, for all signatures Σ and all Σ -sentences ϕ ,

$$\sigma^b_{\Sigma}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)),$$

where $C(\phi)$ is the theory family generated by ϕ . Based on the definition, one is able to show that, roughly speaking, $S^{\mathcal{I}}$ satisfies a kind of congruence property at the level of natural transformations. For instance, it satisfies transitivity, in the sense that, if $\langle \delta^b, \epsilon^b \rangle$ and $\langle \epsilon^b, \zeta^b \rangle$ are pair in $S^{\mathcal{I}}$, then $\langle \delta^b, \zeta^b \rangle$ is also a pair in $S^{\mathcal{I}}$. Additionally, the Suszko core satisfies the property that, for every theory family T of $\mathcal{I}$, $T \leq \overleftarrow{S^{\mathcal{I}}}(\Omega(T))$. The reverse inclusion does not hold in general, but it is one of the key properties that we are looking for. We say that the Suszko core $S^{\mathcal{I}}$ of a π -institution $\mathcal{I}$ is *soluble* if, for every theory family T of $\mathcal{I}$, $\overleftarrow{S^{\mathcal{I}}}(\Omega(T)) \leq T$. Solubility of the Suszko core plays an analogous role to that played by global family modus ponens of the reflexive core in the context of protoalgebraicity. It is, e.g., the property that characterizes truth equationality. More precisely, if $\mathcal{I}$ is truth equational then $S^{\mathcal{I}}$ is soluble and, conversely, if $S^{\mathcal{I}}$ is soluble, then $\mathcal{I}$ is truth equational, with witnessing equations $S^{\mathcal{I}}$.

The last task we set was separating truth equationality from family c-reflectivity. The key property here is the adequacy property of the Suszko core, which corresponds to the Leibniz property of the reflexive core in the context of protoalgebraicity. Briefly, it can be seen that, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : S^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

This inclusion is proper in general. We say that the Suszko core $S^{\mathcal{I}}$ of $\mathcal{I}$ is *adequate* if the reverse inclusion also holds. Note that adequacy of $S^{\mathcal{I}}$ expresses its capability to define Suszko congruence systems in terms of specifically picked Leibniz congruence systems. Solubility of the Suszko core implies its adequacy. Even though this implication is strict in general, the converse holds under the proviso that $\mathcal{I}$ is family c-reflective. Furthermore, adequacy of the Suszko core is the property separating truth equationality from family c-reflectivity, in the sense that $\mathcal{I}$ is truth equational if and only if it is family c-reflective and has an adequate Suszko core. Section 11.8 closes with a transfer theorem for truth equationality.

In Section 11.9, we look at a version of truth equationality and c-reflectivity that do not force the π -institution to be systemic, as is the case with truth equationality and family c-reflectivity, studied in Section 11.8. Recall from Chapter 3, Section 3.8, that a π -institution $\mathcal{I}$ is *left c-reflective* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'},$$

where $\overleftarrow{T}$ denotes the largest theory system included in the theory family T (see Chapter 2). This property is weaker than family c-reflectivity and stronger than system c-reflectivity and is not strong enough to imply systemicity, as is family c-reflectivity. On the other hand, we say that $\mathcal{I}$ is

left truth equational if there exists a collection of natural transformations $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$, with a single distinguished argument, such that, for every theory family T , all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

τ^b are called the *witnessing equations*. Even though, unlike the case of truth equationality, witnessing equations need not reflect theory families, they do so “up to arrow”, i.e., we have, for every theory family T , $\overleftarrow{\tau^b}(\Omega(T)) = \overleftarrow{T}$. This is, however, enough to establish that left truth equationality implies left c-reflectivity. This implication is strict in general. So we seek a characterization of left truth equationality and a condition separating left truth equationality from left c-reflectivity, as done in Section 11.9 for truth equationality and family c-reflectivity. Here, a modified version of the Suszko core $S^\mathcal{I}$ of $\mathcal{I}$ is used. It is called the *left Suszko core* and it is defined by

$$L^\mathcal{I} = \{\sigma^b \in N^b : (\forall T \in \text{ThFam}(\mathcal{I}))(\sigma^b[\overleftarrow{T}] \leq \widetilde{\Omega}^\mathcal{I}(T))\}.$$

The left Suszko core is also called the *system Suszko core*, since it can be equivalently defined by

$$L^\mathcal{I} = \{\sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I}))(\sigma^b[T] \leq \widetilde{\Omega}^\mathcal{I}(T))\}.$$

It is important to observe that, on the one hand, $S^\mathcal{I} \subseteq L^\mathcal{I}$ and, hence, $\overleftarrow{L}^\mathcal{I}(\Omega(T)) \leq \overleftarrow{S}^\mathcal{I}(\Omega(T))$, and that, on the other, in systemic π -institutions, $S^\mathcal{I} = L^\mathcal{I}$. One can show that, for every family T , $\overleftarrow{T} \leq \overleftarrow{L}^\mathcal{I}(\Omega(T))$. In general, this is a proper inclusion. If the reverse inclusion also holds, then $L^\mathcal{I}$ is said to be *left soluble*. This amounts to saying that, for all theory systems T of $\mathcal{I}$, $\overleftarrow{L}^\mathcal{I}(\Omega(T)) = T$. Moreover, for systemic π -institutions, left solubility of the left Suszko core is identical to solubility of the Suszko core. In general, however, the latter is a stronger property than the former. It turns out that left solubility of the left Suszko core characterizes left truth equationality. Further, if $L^\mathcal{I}$ is left soluble, then $L^\mathcal{I}$ acts as a collection of witnessing equations for the left truth equationality of $\mathcal{I}$. We turn, finally, to the task of separating left c-reflectivity from left truth equationality. We show that the left Suszko core $L^\mathcal{I}$ of $\mathcal{I}$ satisfies, for all signatures Σ and all Σ -sentences ϕ ,

$$\bigcap \{\Omega(T) : L_\Sigma^\mathcal{I}[\phi] \leq \Omega(T)\} \leq \widetilde{\Omega}^\mathcal{I}(C(\overrightarrow{\phi})),$$

where $\overrightarrow{\phi}$ is the least sentence system of $\mathcal{I}$ containing ϕ , and that this is a proper inclusion in general. If the reverse inclusion holds, we say that the left Suszko core $L^\mathcal{I}$ is *left adequate*. Left solubility of $L^\mathcal{I}$ implies left adequacy and this is, in general, a strict implication. On the other hand, left adequacy implies left solubility, provided that $\mathcal{I}$ is left c-reflective. More decisively,

$L^{\mathcal{I}}$ is left soluble if and only if $\mathcal{I}$ is left c-reflective and $L^{\mathcal{I}}$ is left adequate. By the equivalence of left truth equationality with left solubility of $L^{\mathcal{I}}$, this yields that left adequacy of $L^{\mathcal{I}}$ is the separating property between left truth equationality and left c-reflectivity.

Section 11.10 continues (and concludes) the work of Sections 11.8 and 11.9, relating versions of truth equationality with those of c-reflectivity. More precisely, we turn to system truth equationality, the weakest version, which, like left truth equationality, can accommodate non-systemic π -institutions. We say that a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is *system c-reflective* if, for every collection $\mathcal{T} \cup \{T'\}$ of theory systems of $\mathcal{I}$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

On the other hand, $\mathcal{I}$ is *system truth equational* if there exists a collection of natural transformations $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$, with a single distinguished argument, called *witnessing equations*, such that, for every theory system T of $\mathcal{I}$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

This property implies that τ^b reflects theory systems, in the sense that, for every theory system T , $\overleftarrow{\tau^b}(\Omega(T)) = T$, which leads to the conclusion that system truth equationality implies system c-reflectivity. Since this implication is strict in general, taking after similar work from Sections 11.8 and 11.9, we provide both a characterization of system truth equationality and of those system c-reflective π -institutions that are system truth equational. The role played by the Suszko core in Section 11.8 and by the left Suszko core in Section 11.9 is played here by the system core of $\mathcal{I}$. For any theory system T of $\mathcal{I}$, define the *systemic Suszko congruence system* of T in $\mathcal{I}$ by

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}(\mathcal{I}) \}.$$

Then define the *system core* of $\mathcal{I}$ by

$$Z^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \widehat{\Omega}^{\mathcal{I}}(T)) \}.$$

It turns out that $S^{\mathcal{I}} \subseteq L^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$. Moreover, we have that, for all theory systems T of $\mathcal{I}$, $T \leq \overleftarrow{Z^{\mathcal{I}}}(\Omega(T))$, this being, in general, a proper inclusion. In case the reverse inclusion also holds, we say that the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is *soluble*. The solubility of the system core characterizes system truth equationality, that is, $\mathcal{I}$ is system truth equational if and only if its system core $Z^{\mathcal{I}}$ is soluble. Finally, to delineate the boundary between system truth equationality and system c-reflectivity, we resort to a property of the system core called adequacy, analogous to the adequacy of the Suszko core and of

the left adequacy of the left Suszko core. In general, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})).$$

If the reverse inclusion also holds, we say that the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is *adequate*. Solubility of $Z^{\mathcal{I}}$ implies its adequacy. Further, if $\mathcal{I}$ is system c-reflective, then adequacy of $Z^{\mathcal{I}}$ implies its solubility. This leads to the promised relation between system truth equationality and system c-reflectivity. Namely, it is shown that $\mathcal{I}$ is system truth equational if and only if it is system c-reflective and has an adequate system core.

11.2 Syntactic Prealgebraicity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 3 that $\mathcal{I}$ is **prealgebraic** if, for all $T, T' \in \text{ThSys}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

We say that $\mathcal{I}$ is **syntactically prealgebraic** if there exists $I^b \subseteq N^b$, with two distinguished arguments, such that I^b has:

- reflexivity;
- global system transitivity;
- global system compatibility;
- global system modus ponens.

In that case, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic prealgebraicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically prealgebraic π -institution, with witnessing transformations I^b , then $\overset{\leftarrow}{I}^b(T)$ is a congruence system on $\mathbf{F}$ compatible with T , for all $T \in \text{ThSys}(\mathcal{I})$. As a consequence, using Corollary 98, we may conclude that, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\overset{\leftarrow}{I}^b(T) = \Omega(T).$$

Proposition 769 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b , then, for all $T \in \text{ThSys}(\mathcal{I})$, $\overset{\leftarrow}{I}^b(T)$ is a congruence system on $\mathbf{F}$ compatible with T .*

Proof: Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$.

Since I^b is reflexive in $\mathcal{I}$, we get that $I_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I}) \leq T$. Therefore, $\vec{I}_\Sigma^b[\phi, \phi] \leq T$, which shows that $\langle \phi, \phi \rangle \in \vec{I}_\Sigma^b(T)$.

Suppose, next, that $\langle \phi, \psi \rangle \in \vec{I}_\Sigma^b(T)$. Thus, $\vec{I}_\Sigma^b[\phi, \psi] \leq T$. By the definition of $\vec{I}^b$, we get $\vec{I}_\Sigma^b[\psi, \phi] \leq T$ and, hence, $\langle \psi, \phi \rangle \in \vec{I}_\Sigma^b(T)$.

Next, assume that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \vec{I}_\Sigma^b(T)$. Then we get $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle, \langle \psi, \phi \rangle, \langle \chi, \psi \rangle \in \vec{I}_\Sigma^b(T)$. Since I^b is globally system transitive in $\mathcal{I}$, we conclude that $\langle \phi, \chi \rangle, \langle \chi, \phi \rangle \in \vec{I}_\Sigma^b(T)$ and, therefore, $\langle \phi, \chi \rangle \in \vec{I}_\Sigma^b(T)$.

To show the congruence property, assume that $\sigma^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ is a natural transformation in N^b and that $\langle \phi_i, \psi_i \rangle \in \vec{I}_\Sigma^b(T)$, for all $i < k$. Thus, since I^b has the global system compatibility in $\mathcal{I}$, we get that $\langle \sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi}) \rangle \in \vec{I}_\Sigma^b(T)$. By symmetry, we also get $\langle \sigma_\Sigma^b(\vec{\psi}), \sigma_\Sigma^b(\vec{\phi}) \rangle \in \vec{I}_\Sigma^b(T)$ and, hence, that $\langle \sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi}) \rangle \in \vec{I}_\Sigma^b(T)$.

Finally, since by Lemma 93, $\vec{I}^b(T)$ is a relation system on $\mathbf{F}$, we conclude that $\vec{I}^b(T)$ is a congruence system on $\mathbf{F}$.

To conclude the proof, note that, if $\phi \in T_\Sigma$ and $\langle \phi, \psi \rangle \in \vec{I}_\Sigma^b(T)$, then $\psi \in T_\Sigma$ by the global system modus ponens of I^b in $\mathcal{I}$ and the fact that $I^b \subseteq \vec{I}^b$. ■

Based on Proposition 769, we can conclude that $\vec{I}^b$ defines the Leibniz congruence systems of the theory systems of $\mathcal{I}$.

Corollary 770 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b , if and only if, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\vec{I}^b(T) = \Omega(T).$$

Proof: The “only if” is by Proposition 769 and Corollary 98. The “if” is obvious, since the displayed equations immediately implies the four properties of $\vec{I}^b$ defining syntactic prealgebraicity. ■

Corollary 770 has as an immediate consequence the important fact that syntactic prealgebraicity implies (semantic) prealgebraicity.

Theorem 771 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically prealgebraic, then it is prealgebraic.*

Proof: Suppose that $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations I^b . Let $T, T' \in \text{ThSys}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{aligned} \Omega(T) &= \overset{\leftarrow}{\overset{\rightarrow}{I^b}}(T) \quad (\text{by Corollary 770}) \\ &\leq \overset{\leftarrow}{\overset{\rightarrow}{I^b}}(T') \quad (\text{by Lemma 94}) \\ &= \Omega(T'). \quad (\text{by Corollary 770}) \end{aligned}$$

Thus, $\mathcal{I}$ is prealgebraic. ■

The following example shows that the inclusion of Theorem 771 is proper.

Example 772 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$, be given, for all $x, y \in \{0, 1\}$, by

$$\sigma_\Sigma^b(x, y) = 1.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, which are also theory systems. Clearly, $\text{Thm}(\mathcal{I}) \leq \mathbf{SEN}^b$. Moreover, $\Omega(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\mathbf{SEN}^b) = \nabla^{\mathbf{F}}$. Since $\Omega(\text{Thm}(\mathcal{I})) \leq \Omega(\mathbf{SEN}^b)$, $\mathcal{I}$ is prealgebraic.

$$\begin{array}{ccc} \mathbf{SEN}^b & \xrightarrow{\quad \quad \quad} & \nabla^{\mathbf{F}} \\ \downarrow & & \downarrow \\ \text{Thm}(\mathcal{I}) & \xrightarrow{\quad \quad \quad} & \Delta^{\mathbf{F}} \end{array}$$

On the other hand, there does not exist $I^b \subseteq N^b$, such that I^b has the required properties to constitute a witnessing set of transformations in $\mathcal{I}$. Any set containing projections cannot satisfy reflexivity and the set consisting only of σ^b does not satisfy the modus ponens property. We conclude that $\mathcal{I}$ is not syntactically prealgebraic.

We provide, next, a characterization of syntactic prealgebraicity in terms of the global system modus ponens property of a subset of natural transformations intrinsically associated with the π -institution. Later, we use this characterization to provide an exact description of those prealgebraic π -institutions which are syntactically prealgebraic.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. We define the **reflexive core** of $\mathcal{I}$ to be the collection

$$R^{\mathcal{I}} = \{ \rho^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \mathbf{SEN}^b(\Sigma))(\rho_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I})) \}.$$

Note that the defining condition is equivalent to asserting that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \bar{\chi} \in \mathbf{SEN}^b(\Sigma)$,

$$\rho_\Sigma^b(\phi, \phi, \bar{\chi}) \in \text{Thm}_\Sigma(\mathcal{I}).$$

It is clear that $\overleftarrow{R}^{\mathcal{I}}(T)$ is a reflexive relation system on $\mathbf{F}$, for every theory family T of $\mathcal{I}$.

Lemma 773 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}}(T)$ is a reflexive relation system on $\mathbf{F}$.*

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. That $\overleftarrow{R}^{\mathcal{I}}(T)$ is a relation system follows from Lemma 93. For reflexivity, it is required that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\langle \phi, \phi \rangle \in \overleftarrow{R}^{\mathcal{I}}_\Sigma(T)$. But this is equivalent to $R_\Sigma^{\mathcal{I}}[\phi, \phi] \leq T$, which certainly holds, since, by definition of $R^{\mathcal{I}}$, $R_\Sigma^{\mathcal{I}}[\phi, \phi] \leq \text{Thm}(\mathcal{I}) \leq T$. ■

Now, using Proposition 97, we draw a useful conclusion about the role of the reflexive core in determining the Leibniz congruence system associated with a given theory family.

Proposition 774 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\Omega(T) \leq \overleftarrow{R}^{\mathcal{I}}(T).$$

Proof: By Lemma 773 and Proposition 97. ■

We next show that, for every theory family T of $\mathcal{I}$, $\overleftarrow{R}^{\mathcal{I}}(T)$ is also a symmetric relation system on $\mathbf{F}$.

Lemma 775 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}}(T)$ is a symmetric relation system on $\mathbf{F}$.*

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. That $\overleftarrow{R}^{\mathcal{I}}(T)$ is a relation system follows from Lemma 93. To show that it is symmetric, let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}}_{\Sigma}(T)$. Equivalently, $R^{\mathcal{I}}_{\Sigma}[\phi, \psi] \leq T$. Now consider any $\rho^b \in R^{\mathcal{I}}$. By the definition of $R^{\mathcal{I}}$, we get that $\bar{\rho}^b \in R^{\mathcal{I}}$. Therefore, by the hypothesis, $\bar{\rho}^b_{\Sigma}[\phi, \psi] \leq T$. But this gives $\rho^b_{\Sigma}[\psi, \phi] \leq T$. Since this holds for all $\rho^b \in R^{\mathcal{I}}$, we conclude that $R^{\mathcal{I}}_{\Sigma}[\psi, \phi] \leq T$. Hence, $\langle \psi, \phi \rangle \in \overleftarrow{R}^{\mathcal{I}}_{\Sigma}(T)$. Therefore, $\overleftarrow{R}^{\mathcal{I}}(T)$ is a symmetric relation system on $\mathbf{F}$. ■

We turn, next, to the congruence compatibility property. More precisely, we show that, for all theory families T of $\mathcal{I}$, $\overleftarrow{R}^{\mathcal{I}}(T)$ has the compatibility property in $\mathbf{F}$.

Lemma 776 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}}(T)$ has the compatibility property in $\mathbf{F}$.*

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. Note that, because of Corollary 12, it suffices to show that, for all $\sigma^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ in N^b , all $\Sigma \in |\mathbf{Sign}^b|$, and all $\phi, \psi, \bar{\chi} \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}}_{\Sigma}(T) \quad \text{implies} \quad \langle \sigma^b_{\Sigma}(\phi, \bar{\chi}), \sigma^b_{\Sigma}(\psi, \bar{\chi}) \rangle \in \overleftarrow{R}^{\mathcal{I}}_{\Sigma}(T).$$

Suppose, $\sigma^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ is in N^b , $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}}_{\Sigma}(T)$ or, equivalently, $R^{\mathcal{I}}_{\Sigma}[\phi, \psi] \leq T$. Let $\rho^b : (\mathbf{SEN}^b)^n \rightarrow \mathbf{SEN}^b$ be arbitrary in $R^{\mathcal{I}}$. We consider the natural transformation $\rho'^b : (\mathbf{SEN}^b)^{n+k} \rightarrow \mathbf{SEN}^b$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\zeta, \eta, \bar{\chi}, \bar{\xi} \in \mathbf{SEN}^b(\Sigma)$, by

$$\rho'^b_{\Sigma}(\zeta, \eta, \bar{\chi}, \bar{\xi}) = \rho^b_{\Sigma}(\sigma^b_{\Sigma}(\zeta, \bar{\chi}), \sigma^b_{\Sigma}(\eta, \bar{\chi}), \bar{\xi}).$$

Now note that, since $\sigma^b \in N^b$, $\rho^b \in N^b$ and

$$\begin{aligned} \rho'^b &= \rho^b \circ \langle \sigma^b \circ \langle p^{n+k,0}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \sigma^b \circ \langle p^{n+k,1}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \\ &\quad p^{n+k,k+1}, \dots, p^{n+k,n+k-1} \rangle, \end{aligned}$$

we get, by the definition of a category of natural transformations, that $\rho'^b \in N^b$.

Next, note that, for all $\Sigma \in |\mathbf{Sign}^b|$, $\zeta, \bar{\chi}, \bar{\xi} \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \rho'^b_{\Sigma}(\zeta, \zeta, \bar{\chi}, \bar{\xi}) &= \rho^b_{\Sigma}(\sigma^b_{\Sigma}(\zeta, \bar{\chi}), \sigma^b_{\Sigma}(\zeta, \bar{\chi}), \bar{\xi}) \quad (\text{by definition of } \rho'^b) \\ &\in \text{Thm}_{\Sigma}(\mathcal{I}). \quad (\text{since } \rho^b \in R^{\mathcal{I}}). \end{aligned}$$

Thus, by the definition of the reflexive core, we get that $\rho'^b \in R^{\mathcal{I}}$.

Now since $\rho'^b \in R^{\mathcal{I}}$ and, by hypothesis, $R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$, we get, in particular, that, for all $\Sigma' \in |\mathbf{Sign}^b|$, and $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$\rho_{\Sigma'}^b(\sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \vec{\chi}), \vec{\xi}) \in T_{\Sigma'}.$$

Hence, a fortiori, for all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma)$, $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$\rho_{\Sigma'}^b(\mathbf{SEN}^b(f)(\sigma_{\Sigma}^b(\phi, \vec{\chi})), \mathbf{SEN}^b(f)(\sigma_{\Sigma}^b(\psi, \vec{\chi})), \vec{\xi}) \in T_{\Sigma'}.$$

This proves that

$$\rho_{\Sigma}^b[\sigma_{\Sigma}^b(\phi, \vec{\chi}), \sigma_{\Sigma}^b(\psi, \vec{\chi})] \leq T.$$

Since this holds for all $\rho^b \in R^{\mathcal{I}}$, we get that $R_{\Sigma}^{\mathcal{I}}[\sigma_{\Sigma}^b(\phi, \vec{\chi}), \sigma_{\Sigma}^b(\psi, \vec{\chi})] \leq T$ or, equivalently, $\langle \sigma_{\Sigma}^b(\phi, \vec{\chi}), \sigma_{\Sigma}^b(\psi, \vec{\chi}) \rangle \in \overleftarrow{R^{\mathcal{I}}_{\Sigma}}(T)$. Therefore, $\overleftarrow{R^{\mathcal{I}}}(T)$ has the congruence compatibility property in $\mathbf{F}$. $\blacksquare$

It is possible, but not necessary, that the reflexive core of a π -institution has the global system modus ponens. To see this, we present two examples. In the first example, we look at a π -institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does have the global system modus ponens in $\mathcal{I}$.

Example 777 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_{\Sigma}^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given by

$$\sigma_{\Sigma}^b(x, y) = \begin{cases} 0, & \text{if } (x, y) = (1, 0) \\ 1, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_{\Sigma} = \{\{1\}, \{0, 1\}\}$. The only theory families, $\mathbf{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, are also theory systems.

Note that $\sigma^b \in R^{\mathcal{I}}$, since, for all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\sigma_{\Sigma}^b(\phi, \phi) = 1 \in \mathbf{Thm}_{\Sigma}(\mathcal{I})$. On the other hand, no projection natural transformation can be in the reflexive core.

To see that $R^{\mathcal{I}}$ satisfies the global system modus ponens in $\mathcal{I}$, note that it does so trivially for the theory system $\mathbf{SEN}^b$, whereas for $\mathbf{Thm}(\mathcal{I})$, it is possible that $\sigma_{\Sigma}^b(\phi, \psi) = 1 \in \mathbf{Thm}_{\Sigma}(\mathcal{I})$ and $\phi = 1 \in \mathbf{Thm}_{\Sigma}(\mathcal{I})$ only if $\psi = 1$. Thus, $R^{\mathcal{I}}$ has the global system MP in $\mathcal{I}$, as claimed.

Next, we present an example of a π -institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does not have the global system modus ponens in $\mathcal{I}$.

Example 778 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given, for all $x, y \in \{0, 1\}$, by

$$\sigma_\Sigma^b(x, y) = 1.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$. So its two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, are also theory systems.

Note that $\sigma^b \in R^\mathcal{I}$, since, for all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$. On the other hand, no projection natural transformation can be in the reflexive core.

To see that $R^\mathcal{I}$ does not satisfy the global system modus ponens in $\mathcal{I}$, note that $1 \in \text{Thm}_\Sigma(\mathcal{I})$ and that $\sigma_\Sigma^b(1, 0) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$ and $\bar{\sigma}^b(1, 0) = \sigma^b(0, 1) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$, but $0 \notin \text{Thm}_\Sigma(\mathcal{I})$. Thus, $R^\mathcal{I}$ does not have the global system MP in $\mathcal{I}$.

It turns out that possession of the global system modus ponens by the reflexive core intrinsically characterizes syntactic prealgebraicity. We can show, at the outset, that the reflexive core having the global system modus ponens is necessary for syntactic prealgebraicity.

Theorem 779 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically prealgebraic, then $R^\mathcal{I}$ has the global system modus ponens.*

Proof: Suppose that $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations I^b . Thus, I^b has reflexivity, global system transitivity, global system compatibility and the global system modus ponens in $\mathcal{I}$. Since I^b is reflexive in $\mathcal{I}$, we get, by the definition of the reflexive core, that $I^b \subseteq R^\mathcal{I}$. But, then, since, by hypothesis, I^b has the global system modus ponens, it follows that, a fortiori, $R^\mathcal{I}$ has the global system modus ponens in $\mathcal{I}$. ■

In proving the reverse implication, we now show that having the global system modus ponens implies the global system transitivity property of the reflexive core.

Proposition 780 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^\mathcal{I}$ has the global system modus ponens, then it also has the global system transitivity in $\mathcal{I}$.*

Proof: Suppose that $R^\mathcal{I}$ has the global system modus ponens in $\mathcal{I}$ and let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftarrow{R^\mathcal{I}_\Sigma}(T)$. This means that $R^\mathcal{I}_\Sigma[\phi, \psi] \leq T$ and $R^\mathcal{I}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 776, we get that, for all $\rho^b \in R^\mathcal{I}$, and all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$R^\mathcal{I}_{\Sigma'}[\rho^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi), \vec{\xi}), \rho^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \mathbf{SEN}^b(f)(\chi), \vec{\xi})] \leq T.$$

Since $R^\mathcal{I}_\Sigma[\phi, \psi] \leq T$, we get by the global system MP of $R^\mathcal{I}$ that, for all $\rho^b \in R^\mathcal{I}$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$\rho^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Thus, $R^\mathcal{I}_\Sigma[\phi, \chi] \leq T$, whence $\langle \phi, \chi \rangle \in \overleftarrow{R^\mathcal{I}_\Sigma}(T)$. Therefore, $R^\mathcal{I}$ has the global system transitivity in $\mathcal{I}$. ■

Proposition 780 closes a line of work that was started with the definition of a reflexive core and with Lemma 773.

Theorem 781 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^\mathcal{I}$ has the global system modus ponens, then $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations $R^\mathcal{I}$.*

Proof: By Lemma 773, $R^{\mathcal{I}}$ is reflexive in $\mathcal{I}$. By Lemma 775, $\mathcal{I}$ is globally family symmetric in $\mathcal{I}$. By hypothesis and Proposition 780, it is globally system transitive in $\mathcal{I}$. By Lemma 776 it has the global family compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the global system modus ponens in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $R^{\mathcal{I}}$. ■

Theorems 779 and 781 provide the promised characterization of syntactic prealgebraicity in terms of the global system modus ponens of the reflexive core.

$\mathcal{I}$ is Syntactically Prealgebraic $\longleftrightarrow R^{\mathcal{I}}$ has Global System MP.

Theorem 782 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic if and only if $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$.*

Proof: Theorem 779 gives the “only if” and the “if” is by Theorem 781. ■

If $\mathcal{I}$ is syntactically prealgebraic, then $R^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 770, since $R^{\mathcal{I}}$ forms a set of witnessing transformations that, in addition, has the global family symmetry in $\mathcal{I}$.

Proposition 783 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global system modus ponens, then, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T).$$

Proof: Let $T \in \text{ThSys}(\mathcal{I})$. If $R^{\mathcal{I}}$ has the global system modus ponens, then, by Lemma 773, Lemma 775, Lemma 776, the hypothesis and Proposition 780, $\overleftarrow{R^{\mathcal{I}}}(T)$ is a congruence system that is compatible with T . Therefore, by Corollary 98, we get that $\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T)$. ■

We also get another related characterization of syntactic prealgebraicity.

$\mathcal{I}$ is Syntactically Prealgebraic
 $\longleftrightarrow R^{\mathcal{I}}$ Defines Leibniz Congruence Systems
of Theory Systems in $\mathcal{I}$.

Theorem 784 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic if and only if, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T).$$

Proof: If $\mathcal{I}$ is syntactically prealgebraic, then, by Theorem 782, $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$. Thus, by Proposition 783, for all $T \in \text{ThSys}(\mathcal{I})$, $\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T)$.

Conversely, if, for all $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{R^{\mathcal{I}}}(T) = \Omega(T)$, then, $R^{\mathcal{I}}$ is reflexive, globally system transitive, has the global family compatibility and the global system modus ponens. Thus, $R^{\mathcal{I}}$ is a set of witnessing transformations and $\mathcal{I}$ is syntactically prealgebraic. ■

We finally show that the property that separates prealgebraicity from syntactic prealgebraicity is exactly the Leibniz compatibility property with respect to the theory system generated by the reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $R^{\mathcal{I}}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])).$$

We show that, if $R^{\mathcal{I}}$ has the global system modus ponens, then it is Leibniz.

Proposition 785 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global system modus ponens, then it is Leibniz.*

Proof: Suppose $R^{\mathcal{I}}$ has the global system modus ponens. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. To show that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]))$, we use the criterion for membership given in Theorem 19. To this end, let $\sigma^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ be in N^b , $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\xi} \in \text{SEN}^b(\Sigma')$, such that

$$\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\xi}) \in C_{\Sigma'}(R_{\Sigma'}^{\mathcal{I}}[\phi, \psi]).$$

By Lemma 776,

$$R_{\Sigma'}^{\mathcal{I}}[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\xi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\xi})] \leq C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]).$$

Since, by hypothesis, $R^{\mathcal{I}}$ has the global system modus ponens, we obtain that $\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\xi}) \in C_{\Sigma'}(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])$. By symmetry, we now have that

$$\begin{aligned} \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\xi}) &\in C_{\Sigma'}(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \\ \text{iff } \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\xi}) &\in C_{\Sigma'}(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]). \end{aligned}$$

Therefore, by Theorem 19, we conclude that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]))$, and, hence, $R^{\mathcal{I}}$ is Leibniz. ■

Here is an example of a π -institution $\mathcal{I}$, with a Leibniz reflexive core not having the global system modus ponens.

Example 786 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $x, y \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and $\mathbf{SEN}^b$, all of which are theory systems.

Note that $R^\mathcal{I} = \{\sigma^b\}$. We show that $R^\mathcal{I}$ is Leibniz, but does not have the global system *modus ponens*.

To verify the Leibniz property, note that, if $\phi = \psi$ the conclusion is trivial. If $\phi \neq \psi$, then, if $\{\phi, \psi\} \neq \{0, 1\}$, then $R_\Sigma^\mathcal{I}[\phi, \psi] = \{\{0\}\}$, whence $C(R_\Sigma^\mathcal{I}[\phi, \psi]) = \mathbf{SEN}^b$ and, therefore,

$$\Omega(C(R_\Sigma^\mathcal{I}[\phi, \psi])) = \nabla^\mathbf{F}$$

and the conclusion follows. Otherwise, if $\{\phi, \psi\} = \{0, 1\}$, then $C(R_\Sigma^\mathcal{I}[\phi, \psi]) = \text{Thm}(\mathcal{I})$, whence

$$\Omega(C(R_\Sigma^\mathcal{I}[\phi, \psi])) = \{\{0, 1\}, \{2\}\}$$

and the conclusion follows. Therefore, $R^\mathcal{I}$ is Leibniz.

On the other hand, we have $1 \in \{1, 2\}$ and $R_\Sigma^\mathcal{I}[1, 0] \leq \{\{1, 2\}\}$, whereas $0 \notin \{1, 2\}$. Therefore, $R^\mathcal{I}$ fails to have the global system *modus ponens* in $\mathcal{I}$.

We note, with a nod to what is to follow, that $\mathcal{I}$ is not prealgebraic, since, as is clear by the poset diagrams of theory systems and associated Leibniz

congruence systems, the Leibniz operator is not monotone on theory systems (here $\theta = \{\{0\}, \{1, 2\}\}$ and $\theta' = \{\{0, 1\}, \{2\}\}$).

In the opposite direction, and on the positive side, in a *prealgebraic* π -institution $\mathcal{I}$, if the reflexive core is Leibniz, then it does have the global system modus ponens in $\mathcal{I}$.

Proposition 787 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a prealgebraic π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ is Leibniz, then it has the global system modus ponens in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is prealgebraic and that $R^{\mathcal{I}}$ is Leibniz. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $R_\Sigma^{\mathcal{I}}[\phi, \psi] \leq T$. Now we have

$$\begin{aligned} \langle \phi, \psi \rangle &\in \Omega_\Sigma(C(R_\Sigma^{\mathcal{I}}[\phi, \psi])) \quad (\text{since } R^{\mathcal{I}} \text{ is Leibniz}) \\ &\subseteq \Omega_\Sigma(T). \quad (\text{since } R_\Sigma^{\mathcal{I}}[\phi, \psi] \leq T \text{ and } \mathcal{I} \text{ is prealgebraic}) \end{aligned}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T , that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}}$ has the global system modus ponens in $\mathcal{I}$. ■

We now show that a π -institution is syntactically prealgebraic if and only if it is prealgebraic and it has a Leibniz reflexive core.

$$\begin{aligned} \text{Syntactic Prealgebraicity} &= R^{\mathcal{I}} \text{ has Global System MP} \\ &= R^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ &\quad \text{of Theorem Systems in } \mathcal{I} \\ &= \text{Prealgebraicity} + R^{\mathcal{I}} \text{ is Leibniz} \end{aligned}$$

Theorem 788 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic if and only if it is prealgebraic and has a Leibniz reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically prealgebraic. By Theorem 771, it is prealgebraic. Moreover, by Theorem 782, its reflexive core has the global system modus ponens. Hence, by Proposition 785, its reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is prealgebraic with a Leibniz reflexive core. Then, by Proposition 787, its reflexive core has the global system modus ponens and, therefore, by Theorem 782, $\mathcal{I}$ is syntactically prealgebraic. ■

It is not difficult to see that syntactic prealgebraicity transfers from a π -institution $\mathcal{I}$ to all models of $\mathcal{I}$ of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ over arbitrary $\mathbf{F}$ -algebraic systems.

Theorem 789 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the generalized matrix family $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically prealgebraic, with witnessing transformations $I^{\mathcal{A}}$.*

Proof: We have that $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b , if and only if, by definition, I^b is reflexive, has the global system transitivity, the global system compatibility and the global system modus ponens, if and only if, by Propositions 683, 693, 715 and 1477, for every $\mathbf{F}$ -algebraic system, $I^{\mathcal{A}}$ has reflexivity, global system transitivity, global system compatibility and global system modus ponens in $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ if and only if, by definition, $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically prealgebraic, with witnessing transformations $I^{\mathcal{A}}$. ■

11.3 Syntactic Protoalgebraicity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Recall from Chapter 3 that $\mathcal{I}$ is *protoalgebraic* if, for all $T, T' \in \text{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

We say that $\mathcal{I}$ is **syntactically protoalgebraic** if there exists $I^b \subseteq N^b$, with two distinguished arguments, such that I^b has:

- reflexivity;
- global family transitivity;
- global family compatibility;
- global family modus ponens.

In that case, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic protoalgebraicity of $\mathcal{I}$).

Let us compare syntactic protoalgebraicity with the definition of syntactic prealgebraicity from Section 11.2. We point out that, by Chapter 10, Sections 10.5 and 10.9, respectively, global family and global system transitivity and global family and global system compatibility coincide. It follows that the genuinely separating feature between syntactic prealgebraicity and syntactic protoalgebraicity is that the former requires the global system modus ponens, whereas the latter the global family modus ponens. By the subhierarchy of modus ponens properties, presented in Section 10.11, the latter is a strictly stronger property than the former.

It turns out that, if $\mathcal{I}$ is a syntactically protoalgebraic π -institution, with witnessing transformations I^b , then $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$ compatible with T , for all $T \in \text{ThFam}(\mathcal{I})$. As a consequence, using Corollary 98, we may conclude that, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\overleftrightarrow{I^b}(T) = \Omega(T).$$

Proposition 790 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations I^b , then, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$ compatible with T .*

Proof: Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$.

Since I^b is reflexive in $\mathcal{I}$, we get that $I_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I}) \leq T$. Therefore, $\overleftrightarrow{I^b}_\Sigma[\phi, \phi] \leq T$, which shows that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$.

Suppose, next, that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. Thus, $\overleftrightarrow{I^b}_\Sigma[\phi, \psi] \leq T$. By the definition of $\overleftrightarrow{I^b}$, we then get $\overleftrightarrow{I^b}_\Sigma[\psi, \phi] \leq T$ and, hence, $\langle \psi, \phi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$.

Next, assume that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. Then we get $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle, \langle \psi, \phi \rangle, \langle \chi, \psi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. Since I^b is transitive in $\mathcal{I}$, we conclude that $\langle \phi, \chi \rangle, \langle \chi, \phi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$ and, therefore, $\langle \phi, \chi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$.

To show the congruence property, assume that $\sigma^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ is a natural transformation in N^b and that $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$, for all $i < k$. Thus, since I^b has the compatibility property in $\mathcal{I}$, we get that $\langle \sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi}) \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. By symmetry, we also get $\langle \sigma_\Sigma^b(\vec{\psi}), \sigma_\Sigma^b(\vec{\phi}) \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$ and, hence, that $\langle \sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi}) \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$.

Finally, since by Lemma 93, $\overleftrightarrow{I^b}(T)$ is a relation system on $\mathbf{F}$, we conclude that $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$.

To conclude the proof, note that, if $\phi \in T_\Sigma$ and $\langle \phi, \psi \rangle \in \overset{\leftarrow}{\overleftrightarrow{I}}^\flat_\Sigma(T)$, then, by the global family modus ponens of $I^\flat$ in $\mathcal{I}$ and the fact that $I^\flat \subseteq \overset{\leftarrow}{\overleftrightarrow{I}}^\flat$, $\psi \in T_\Sigma$. ■

Based on Proposition 790, we can conclude that $\overset{\leftarrow}{\overleftrightarrow{I}}^\flat$ defines the Leibniz congruence systems of the theory families of $\mathcal{I}$.

Corollary 791 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathbf{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations $I^\flat$, if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overset{\leftarrow}{\overleftrightarrow{I}}^\flat(T) = \Omega(T).$$

Proof: The “only if” is by Proposition 790 and Corollary 98. The “if” is again obvious, as in Corollary 770. ■

Corollary 791 has as an immediate consequence the important fact that syntactic protoalgebraicity implies (semantic) protoalgebraicity.

Theorem 792 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathbf{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, then it is protoalgebraic.*

Proof: Suppose that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $I^\flat$. Let $T, T' \in \text{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{aligned} \Omega(T) &= \overset{\leftarrow}{\overleftrightarrow{I}}^\flat(T) \quad (\text{by Corollary 791}) \\ &\leq \overset{\leftarrow}{\overleftrightarrow{I}}^\flat(T') \quad (\text{by Lemma 94}) \\ &= \Omega(T'). \quad (\text{by Corollary 791}) \end{aligned}$$

Thus, $\mathcal{I}$ is protoalgebraic. ■

The following example shows that the inclusion of Theorem 792 is proper.

Example 793 *Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathbf{SEN}^\flat, N^\flat \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^\flat$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^\flat : \mathbf{Sign}^\flat \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^\flat(\Sigma) = \{0, 1\}$;
- $N^\flat$ is the category of natural transformations generated by the single binary natural transformation $\sigma^\flat : (\mathbf{SEN}^\flat)^2 \rightarrow \mathbf{SEN}^\flat$ defined by letting $\sigma_\Sigma^\flat : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given, for all $x, y \in \{0, 1\}$, by

$$\sigma_\Sigma^\flat(x, y) = 1.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , such that $\text{Thm}(\mathcal{I}) \leq \text{SEN}^b$. Moreover, $\Omega(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\text{SEN}^b) = \nabla^{\mathbf{F}}$. Since $\Omega(\text{Thm}(\mathcal{I})) \leq \Omega(\text{SEN}^b)$, $\mathcal{I}$ is protoalgebraic.

$$\begin{array}{ccc}
 \text{SEN}^b & \xrightarrow{\dots\dots\dots} & \nabla^{\mathbf{F}} \\
 | & & | \\
 \text{Thm}(\mathcal{I}) & \xrightarrow{\dots\dots\dots} & \Delta^{\mathbf{F}}
 \end{array}$$

On the other hand, there does not exist $I^b \subseteq N^b$, such that I^b has the required properties to constitute a witnessing set of transformations in $\mathcal{I}$. Any set containing projections cannot satisfy reflexivity and the set consisting only of σ^b does not satisfy the modus ponens property. We conclude that $\mathcal{I}$ is not syntactically protoalgebraic.

We now work towards a dual goal. We first provide a characterization of syntactic protoalgebraicity in terms of the global family modus ponens of the reflexive core of the π -institution. Then, we use this characterization to provide an exact description of those protoalgebraic π -institutions which are syntactically protoalgebraic. The development here parallels the work done, towards similar goals in the context of prealgebraicity, in Section 11.2.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Section 11.2, that the reflexive core of $\mathcal{I}$ is the collection

$$R^{\mathcal{I}} = \{\rho^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \text{SEN}^b(\Sigma))(\rho_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I}))\}.$$

It is possible, but not necessary, that the reflexive core of a π -institution has the global family modus ponens. To see this, we present two examples. In the first example, we look at a π -institution $\mathcal{I}$ whose reflexive core $R^{\mathcal{I}}$ does have the global family modus ponens in $\mathcal{I}$.

Example 794 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given, for all $x, y \in \{0, 1\}$, by

$$\sigma_\Sigma^b(x, y) = \begin{cases} 0, & \text{if } (x, y) = (1, 0) \\ 1, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_\Sigma = \{\{1\}, \{0, 1\}\}$.

Note that $\sigma^b \in R^\mathcal{I}$, since, for all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$. On the other hand, no projection natural transformation can be in the reflexive core.

To see that $R^\mathcal{I}$ satisfies the modus ponens in $\mathcal{I}$, note that it does so trivially for the theory family $\mathbf{SEN}^b$, whereas for $\text{Thm}(\mathcal{I})$, it is possible that $\sigma_\Sigma^b(\phi, \psi) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$ and $\phi = 1 \in \text{Thm}_\Sigma(\mathcal{I})$ only if $\psi = 1$. Thus, $R^\mathcal{I}$ has the global family MP in $\mathcal{I}$, as claimed.

Next, we present an example of a π -institution $\mathcal{I}$ whose reflexive core $R^\mathcal{I}$ does not have the global family modus ponens in $\mathcal{I}$.

Example 795 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;

- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1\}^2 \rightarrow \{0, 1\}$ be given, for all $x, y \in \{0, 1\}$, by

$$\sigma_\Sigma^b(x, y) = 1.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

Note that $\sigma^b \in R^\mathcal{I}$, since, for all $\phi \in \text{SEN}^b(\Sigma)$, $\sigma_\Sigma^b(\phi, \phi) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$. On the other hand, no projection natural transformation can be in the reflexive core.

To see that $R^\mathcal{I}$ does not satisfy the modus ponens in $\mathcal{I}$, note that $1 \in \text{Thm}_\Sigma(\mathcal{I})$ and that $\sigma_\Sigma^b(1, 0) = \sigma_\Sigma^b(0, 1) = 1 \in \text{Thm}_\Sigma(\mathcal{I})$, but $0 \notin \text{Thm}_\Sigma(\mathcal{I})$. Thus, $R^\mathcal{I}$ does not have the global family modus ponens in $\mathcal{I}$.

It turns out that possession of the global family modus ponens by the reflexive core intrinsically characterizes syntactic protoalgebraicity. We can show, at the outset, that the reflexive core having the global family modus ponens is necessary for syntactic protoalgebraicity. Thus, there is no point in exploring syntactic protoalgebraicity unless the π -institution $\mathcal{I}$ under scrutiny is such that $R^\mathcal{I}$ has the global family MP.

Theorem 796 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, then $R^\mathcal{I}$ has the global family modus ponens.

Proof: Suppose that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations I^b . Thus, I^b has reflexivity, global family transitivity, global family compatibility and the global family modus ponens in $\mathcal{I}$. Since I^b is reflexive in $\mathcal{I}$, we get, by the definition of the reflexive core, that $I^b \subseteq R^\mathcal{I}$. But, then, since, by hypothesis, I^b has the global family modus ponens, it follows that, a fortiori, $R^\mathcal{I}$ has the global family modus ponens in $\mathcal{I}$. ■

To prove the reverse implication, we show, first, that having the global family modus ponens implies the global family transitivity property of the reflexive core.

Proposition 797 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^\mathcal{I}$ has the global family modus ponens, then it also has the global family transitivity in $\mathcal{I}$.*

Proof: Suppose that $R^\mathcal{I}$ has the global family modus ponens in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftarrow{R^\mathcal{I}}_\Sigma(T)$. This means that $R^\mathcal{I}_\Sigma[\phi, \psi] \leq T$ and $R^\mathcal{I}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 776, we get that, for all $\rho^b \in R^\mathcal{I}$, and all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$R^\mathcal{I}_{\Sigma'}[\rho^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi), \vec{\xi}), \rho^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\chi), \vec{\xi})] \leq T.$$

Since $R^\mathcal{I}_\Sigma[\phi, \psi] \leq T$, we get by the global family MP of $R^\mathcal{I}$ that, for all $\rho^b \in R^\mathcal{I}$, and all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$\rho^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'}.$$

Thus, $R^\mathcal{I}_\Sigma[\phi, \chi] \leq T$, whence $\langle \phi, \chi \rangle \in \overleftarrow{R^\mathcal{I}}_\Sigma(T)$. Therefore $R^\mathcal{I}$ is globally family transitive in $\mathcal{I}$. ■

Proposition 797 closes a line of work that was started with the definition of a reflexive core and goes back to Lemma 773.

Theorem 798 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^\mathcal{I}$ has the global family modus ponens, then $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations $R^\mathcal{I}$.*

Proof: By Lemma 773, $R^\mathcal{I}$ is reflexive in $\mathcal{I}$. By Lemma 775, $\mathcal{I}$ is globally family symmetric in $\mathcal{I}$. By hypothesis and Proposition 797, it is globally family transitive in $\mathcal{I}$. By Lemma 776, it has the global family compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the global family modus ponens in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $R^\mathcal{I}$. ■

Theorems 796 and 798 provide the promised characterization of syntactic protoalgebraicity in terms of the global family modus ponens of the reflexive core.

$\mathcal{I}$ is Syntactically Protoalgebraic $\longleftrightarrow R^\mathcal{I}$ has Global Family MP.

Theorem 799 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if $R^\mathcal{I}$ has the global family modus ponens in $\mathcal{I}$.*

Proof: Theorem 796 gives the “only if” and the “if” is by Theorem 798. ■

If $\mathcal{I}$ is syntactically protoalgebraic, then $R^{\mathcal{I}}$ defines Leibniz congruence systems in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 791, since $R^{\mathcal{I}}$ forms a set of witnessing transformations that, in addition, has the global family symmetry in $\mathcal{I}$.

Proposition 800 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global family modus ponens, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T).$$

Proof: If $R^{\mathcal{I}}$ has the global family modus ponens, then, by Lemma 773, Lemma 775, Lemma 776, the hypothesis and Proposition 797, $\overleftarrow{R^{\mathcal{I}}}(T)$ is a congruence system that is compatible with T . Therefore, by Corollary 98, we get that $\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T)$. ■

We also get (almost) for free another related characterization of syntactic protoalgebraicity.

$\mathcal{I}$ is Syntactically Protoalgebraic

$\longleftrightarrow R^{\mathcal{I}}$ Defines Leibniz Congruence Systems.

Theorem 801 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T).$$

Proof: If $\mathcal{I}$ is syntactically protoalgebraic, then, by Theorem 799, $R^{\mathcal{I}}$ has the family modus ponens in $\mathcal{I}$. Thus, by Proposition 800, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T)$.

Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{R^{\mathcal{I}}}(T) = \Omega(T)$, then, $R^{\mathcal{I}}$ is reflexive, globally family transitive, has the global family compatibility and the global family modus ponens. Thus, $R^{\mathcal{I}}$ is a set of witnessing transformations and $\mathcal{I}$ is syntactically protoalgebraic. ■

We finally show, in a result that parallels Theorem 788, that the property that separates protoalgebraicity from syntactic protoalgebraicity is exactly the Leibniz compatibility property with respect to the theory family generated by the reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Section 11.2 that $R^{\mathcal{I}}$ is *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R^{\mathcal{I}}_{\Sigma}[\phi, \psi])).$$

We have shown in Proposition 785 that, if $R^{\mathcal{I}}$ has the global system modus ponens, then it is Leibniz.

Corollary 802 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}}$ has the global family modus ponens, then it is Leibniz.*

Proof: Directly from Proposition 785 ■

Here is an example of a π -institution $\mathcal{I}$, with a Leibniz reflexive core not having the global family modus ponens.

Example 803 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_{\Sigma}^b : \{0, 1, 2\}^2 \rightarrow \{0, 1, 2\}$ be given, for all $x, y \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_{\Sigma}^b(x, y) = \begin{cases} 2, & \text{if } x = y \text{ or } \{x, y\} = \{0, 1\} \\ 0, & \text{otherwise} \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_{\Sigma} = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and $\mathbf{SEN}^b$, but only two theory systems $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$.

Note that $R^{\mathcal{I}} = \{\sigma^b\}$. We show that $R^{\mathcal{I}}$ is Leibniz, but does not have the global family modus ponens.

To verify the Leibniz property, note that, if $\phi = \psi$ the conclusion is trivial and, if $\{\phi, \psi\} \neq \{0, 1\}$, then $C_\Sigma(R_\Sigma^\mathcal{I}[\phi, \psi]) = \text{SEN}^b(\Sigma)$, whence

$$\Omega(C(R_\Sigma^\mathcal{I}[\phi, \psi])) = \nabla^{\mathbf{F}}$$

and the conclusion follows. Finally, if $\{\phi, \psi\} = \{0, 1\}$, then $C_\Sigma(R_\Sigma^\mathcal{I}[\phi, \psi]) = \{2\}$, whence $\Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi])) = \{\{0, 1\}, \{2\}\}$ and, therefore,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi])),$$

as required. We conclude that $R^\mathcal{I}$ is Leibniz.

On the other hand, we have $1 \in \{1, 2\}$ and $R_\Sigma^\mathcal{I}[1, 0] \leq \{\{1, 2\}\}$, whereas $0 \notin \{1, 2\}$. Therefore, $R^\mathcal{I}$ fails to have the global family modus ponens in $\mathcal{I}$.

In the opposite direction, and on the positive side, in a protoalgebraic π -institution $\mathcal{I}$, if the reflexive core is Leibniz, then it has the global family modus ponens in $\mathcal{I}$.

Proposition 804 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. If $R^\mathcal{I}$ is Leibniz, then it has the global family modus ponens in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is protoalgebraic and that $R^\mathcal{I}$ is Leibniz. Let $\Sigma \in |\text{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $R_\Sigma^\mathcal{I}[\phi, \psi] \leq T$. Now we have

$$\begin{aligned} \langle \phi, \psi \rangle &\in \Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi])) \quad (\text{since } R^\mathcal{I} \text{ is Leibniz}) \\ &\subseteq \Omega_\Sigma(T). \quad (\text{since } R_\Sigma^\mathcal{I}[\phi, \psi] \leq T \text{ and } \mathcal{I} \text{ is protoalgebraic}) \end{aligned}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T , that $\psi \in T_\Sigma$. We conclude that $R^\mathcal{I}$ has the global family modus ponens in $\mathcal{I}$. ■

We now show that a π -institution is syntactically protoalgebraic if and only if it is protoalgebraic and has a Leibniz reflexive core.

$$\begin{aligned} \text{Syntactic Protoalgebraicity} &= R^\mathcal{I} \text{ has Global Family MP} \\ &= R^\mathcal{I} \text{ Defines Leibniz Congruence Systems} \\ &= \text{Protoalgebraicity} + R^\mathcal{I} \text{ is Leibniz} \end{aligned}$$

Theorem 805 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if it is protoalgebraic and has a Leibniz reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically protoalgebraic. Then, by Theorem 792, it is protoalgebraic. Moreover, by Theorem 799, its reflexive core

has the global family modus ponens. Hence, by Corollary 802, its reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is protoalgebraic with a Leibniz reflexive core. Then, by Proposition 804, its reflexive core has the global family modus ponens and, therefore, by Theorem 799, $\mathcal{I}$ is syntactically protoalgebraic. ■

We have now established the following hierarchy of properties:

In fact, it turns out that many of the given characterizations of syntactic protoalgebraicity can be recast in terms of the corresponding ones concerning syntactic prealgebraicity by adding stability. The main result that allows this connection is the one corresponding to Theorem 175, but concerning syntactic protoalgebraicity and syntactic prealgebraicity rather than their respective semantic versions.

Theorem 806 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if it is syntactically prealgebraic and stable.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically protoalgebraic. Then, it is, a fortiori, syntactically prealgebraic. Moreover, by Theorem 792, it is protoalgebraic. Therefore, by Theorem 175, it is stable.

Suppose, conversely, that $\mathcal{I}$ is syntactically prealgebraic and stable. Consider $T \in \text{ThFam}(\mathcal{I})$. Then we have

$$\begin{aligned}
 \Omega(T) &= \Omega(\overleftarrow{T}) \quad (\text{stability}) \\
 &= \overleftarrow{R^{\mathcal{I}}}(\overleftarrow{T}) \quad (\text{syntactic prealgebraicity and Theorem 784}) \\
 &= \overleftarrow{R^{\mathcal{I}}}(T). \quad (\text{Proposition 99})
 \end{aligned}$$

By Theorem 801, we conclude that $\mathcal{I}$ is syntactically protoalgebraic. ■

Now we obtain, almost for free, the following corollaries, which contain the promised characterizations involving stability.

Corollary 807 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if it is stable and $R^{\mathcal{I}}$ has the global system modus ponens.*

Proof: We have that $\mathcal{I}$ is syntactically protoalgebraic if and only if, by Theorem 806, it is syntactically prealgebraic and stable, if and only if, by Theorem 782, it is stable and $R^{\mathcal{I}}$ has the global system modus ponens. ■

Corollary 808 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if it is stable and $R^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems of $\mathcal{I}$, i.e., for all $T \in \text{ThSys}(\mathcal{I})$, $\Omega(T) = \overleftarrow{R^{\mathcal{I}}}(T)$.*

Proof: We have that $\mathcal{I}$ is syntactically protoalgebraic if and only if, by Theorem 806, it is syntactically prealgebraic and stable, if and only if, by Theorem 784, it is stable and $R^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems in $\mathcal{I}$. ■

Corollary 809 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic if and only if it is prealgebraic, stable and $R^{\mathcal{I}}$ is Leibniz.*

Proof: We have that $\mathcal{I}$ is syntactically protoalgebraic if and only if, by Theorem 806, it is syntactically prealgebraic and stable, if and only if, by Theorem 788, it is prealgebraic, stable and $R^{\mathcal{I}}$ is Leibniz. ■

Finally, it is not difficult to see, in this case as well, that syntactic protoalgebraicity transfers from a π -institution $\mathcal{I}$ to all generalized matrix families of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Theorem 810 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations I^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the generalized matrix family $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically protoalgebraic, with witnessing transformations $I^{\mathcal{A}}$.*

Proof: The proof mimics the proof of Theorem 789. ■

We close with an example of a π -institution that is syntactically prealgebraic but not syntactically protoalgebraic.

Example 811 EXAMPLE NOT FOUND YET!!

11.4 Matrix Semantics

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Section 2.7 of Chapter 2 that an $\mathcal{I}$ -matrix family is a pair $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$ -algebraic system

and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is an $\mathcal{I}$ -filter family on $\mathcal{A}$. The class of all $\mathcal{I}$ -matrix families is denoted by $\text{MatFam}(\mathcal{I})$. $\mathcal{I}$ -matrix families on $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, i.e., pairs of the form $\langle \mathcal{F}, T \rangle$, where $T \in \text{ThFam}(\mathcal{I})$, are called **Lindenbaum $\mathcal{I}$ -matrix families**. The collection of all Lindenbaum $\mathcal{I}$ -matrix families is denoted by $\text{LMatFam}(\mathcal{I})$.

Four subclasses of $\text{MatFam}(\mathcal{I})$ are distinguished and will be of particular interest to us in the upcoming sections. These are:

- The class $\text{LMatFam}^*(\mathcal{I})$ of all **reduced Lindenbaum $\mathcal{I}$ -matrix families**:

$$\text{LMatFam}^*(\mathcal{I}) = \{ \langle \mathcal{F}/\Omega(T), T/\Omega(T) \rangle : T \in \text{ThFam}(\mathcal{I}) \};$$

- The class $\text{LMatFam}^{\text{Su}}(\mathcal{I})$ of all **Suszko reduced Lindenbaum $\mathcal{I}$ -matrix families**:

$$\text{MatFam}^{\text{Su}}(\mathcal{I}) = \{ \langle \mathcal{F}/\tilde{\Omega}^{\mathcal{I}}(T), T/\tilde{\Omega}^{\mathcal{I}}(T) \rangle : T \in \text{ThFam}(\mathcal{I}) \};$$

- The class $\text{MatFam}^*(\mathcal{I})$ of all **reduced $\mathcal{I}$ -matrix families**:

$$\text{LMatFam}^*(\mathcal{I}) = \{ \langle \mathcal{A}, T \rangle \in \text{MatFam}(\mathcal{I}) : \Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}} \};$$

- The class $\text{MatFam}^{\text{Su}}(\mathcal{I})$ of all **Suszko reduced $\mathcal{I}$ -matrix families**:

$$\text{MatFam}^{\text{Su}}(\mathcal{I}) = \{ \langle \mathcal{A}, T \rangle \in \text{MatFam}(\mathcal{I}) : \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \Delta^{\mathcal{A}} \}.$$

The following characterizations of the last two classes are well-known and very useful in practice.

Proposition 812 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then the following equalities hold (where the classes are perceived as being closed under isomorphism):*

$$(a) \text{ MatFam}^*(\mathcal{I}) = \{ \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle : T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \};$$

$$(b) \text{ MatFam}^{\text{Su}}(\mathcal{I}) = \{ \langle \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T), T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \rangle : T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \}.$$

Proof: We prove Part (a). Part (b) can be proven similarly. First, if $\langle \mathcal{A}, T \rangle \in \text{MatFam}^*(\mathcal{I})$, then, since, by definition, $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$, we get that $\langle \mathcal{A}, T \rangle \cong \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle$. For the reverse inclusion, it suffices to observe that, given an $\mathbf{F}$ -algebraic system $\mathcal{A}$ and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have, essentially due to the definition of the Leibniz congruence system, that

$$\Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}.$$

Therefore, $\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle \in \text{MatFam}^*(\mathcal{I})$. ■

It turns out that all four classes of $\mathcal{I}$ -matrix families defined above form matrix family semantics for the π -institution $\mathcal{I}$. More precisely, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ and a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, a class M of $\mathcal{I}$ -matrix families is called a **matrix (family) semantics for $\mathcal{I}$** if $C = C^M$, i.e., for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, $\phi \in C_\Sigma(\Phi)$ if and only if, for all $\langle \mathcal{A}, T \rangle \in M$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) \in T_{F(\Sigma')}.$$

Proposition 813 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathcal{I}$. The four classes*

$$\text{LMatFam}^*(\mathcal{I}), \text{LMatFam}^{\text{Su}}(\mathcal{I}), \text{MatFam}^*(\mathcal{I}) \text{ and } \text{MatFam}^{\text{Su}}(\mathcal{I})$$

are all matrix semantics for $\mathcal{I}$.

Proof: Let M be any of these four matrix family classes. Since M consists of $\mathcal{I}$ -matrix families, we have that $C \leq C^M$.

For the converse, note that the following inclusions hold:

$$\begin{array}{ccc} & \text{LMatFam}^{\text{Su}}(\mathcal{I}) & \\ & \searrow & \\ & \text{MatFam}^{\text{Su}}(\mathcal{I}) & \\ \text{LMatFam}^*(\mathcal{I}) & \longrightarrow & \text{MatFam}^*(\mathcal{I}) \end{array}$$

Therefore, we have, by definition, the inclusions

$$\begin{array}{ccc} & C^{\text{LMatFam}^{\text{Su}}(\mathcal{I})} & \\ & \nearrow & \\ C^{\text{MatFam}^{\text{Su}}(\mathcal{I})} & & \\ & \searrow & \\ & C^{\text{MatFam}^*(\mathcal{I})} \longrightarrow C^{\text{LMatFam}^*(\mathcal{I})} & \end{array}$$

It follows that it suffices to show that the two reduced Lindenbaum matrix family classes satisfy $C^{\text{LMatFam}^{\text{Su}}(\mathcal{I})} \leq C$ and $C^{\text{LMatFam}^*(\mathcal{I})} \leq C$. We show the first inclusion, since the second can be proven similarly.

Suppose $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that

$$\phi \in C_\Sigma^{\text{LMatFam}^{\text{Su}}(\mathcal{I})}(\Phi).$$

Let $T \in \text{ThFam}(\mathcal{I})$, such that $\Phi \subseteq T_\Sigma$. Then, $\Phi/\tilde{\Omega}_\Sigma^\mathcal{I}(T) \subseteq T_\Sigma/\tilde{\Omega}_\Sigma^\mathcal{I}(T)$. Since $\langle \mathcal{F}/\tilde{\Omega}^\mathcal{I}(T), T/\tilde{\Omega}^\mathcal{I}(T) \rangle \in \text{LMatFam}^{\text{Su}}(\mathcal{I})$, we get, by hypothesis, $\phi/\tilde{\Omega}_\Sigma^\mathcal{I}(T) \in T_\Sigma/\tilde{\Omega}_\Sigma^\mathcal{I}(T)$. Thus, using the compatibility of $\tilde{\Omega}^\mathcal{I}(T)$ with T , we get that $\phi \in T_\Sigma$. Since $T \in \text{ThFam}(\mathcal{I})$ was arbitrary, we conclude that $\phi \in C_\Sigma(\Phi)$. ■

We denote the classes of the underlying $\mathbf{F}$ -algebraic systems of the matrix families in $\text{LMatFam}^*(\mathcal{I})$, $\text{LMatFam}^{\text{Su}}(\mathcal{I})$, $\text{MatFam}^*(\mathcal{I})$ and $\text{MatFam}^{\text{Su}}(\mathcal{I})$, respectively, by

$$\text{LAlgSys}^*(\mathcal{I}), \text{LAlgSys}^{\text{Su}}(\mathcal{I}), \text{AlgSys}^*(\mathcal{I}) \text{ and } \text{AlgSys}^{\text{Su}}(\mathcal{I}).$$

So we have

$$\begin{aligned} \text{LAlgSys}^*(\mathcal{I}) &= \{\mathcal{F}/\Omega(T) : T \in \text{ThFam}(\mathcal{I})\}; \\ \text{LAlgSys}^{\text{Su}}(\mathcal{I}) &= \{\mathcal{F}/\tilde{\Omega}^{\mathcal{I}}(T) : T \in \text{ThFam}(\mathcal{I})\}; \\ \text{AlgSys}^*(\mathcal{I}) &= \{\mathcal{A} : (\exists T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}})\}; \\ \text{AlgSys}^{\text{Su}}(\mathcal{I}) &= \{\mathcal{A} : (\exists T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}))(\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \Delta^{\mathcal{A}})\}. \end{aligned}$$

We clearly have the following inclusion relationships between those four classes of $\mathbf{F}$ -algebraic systems:

$$\begin{array}{ccc} & \text{LAlgSys}^{\text{Su}}(\mathcal{I}) & \\ & \searrow & \\ & \text{AlgSys}^{\text{Su}}(\mathcal{I}) & \\ \text{LAlgSys}^*(\mathcal{I}) \longrightarrow & \text{AlgSys}^*(\mathcal{I}) & \nearrow \end{array}$$

11.5 Algebraic Semantics

In the study of logical systems formalized as π -institutions and, more specifically, as related to their algebraic properties, the notions of an algebraic semantics and that of equational definability of truth are paramount. We introduce and study these two notions in this section.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Consider a class K of $\mathbf{F}$ -algebraic systems. We define the closure family $C^K : \mathcal{P}(\text{SEN}^b)^2 \rightarrow \mathcal{P}(\text{SEN}^b)^2$, by letting, for all $\Sigma \in |\mathbf{Sign}^b|$, $C_{\Sigma}^K : \mathcal{P}(\text{SEN}^b(\Sigma)^2) \rightarrow \mathcal{P}(\text{SEN}^b(\Sigma)^2)$ be given, for all $E \cup \{\phi \approx \psi\} \subseteq \text{SEN}^b(\Sigma)^2$, by

$$\begin{aligned} \phi \approx \psi \in C_{\Sigma}^K(E) \quad \text{iff} \quad & \text{for all } \mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in K, \\ & \alpha_{\Sigma}(E) \subseteq \Delta_{F(\Sigma)}^{\mathcal{A}} \text{ implies } \alpha_{\Sigma}(\phi) = \alpha_{\Sigma}(\psi). \end{aligned}$$

Given a set $\tau^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with a single distinguished argument, we say that the class K of $\mathbf{F}$ -algebraic systems is a τ^b -**algebraic semantics for** $\mathcal{I}$, or, more simply, a τ^b -**semantics for** $\mathcal{I}$, if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in C_{\Sigma}(\Phi) \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq C^K(\tau_{\Sigma}^b[\Phi]).$$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution, based on $\mathbf{F}$, and M a class of $\mathbf{F}$ -matrix families. Given a set $\tau^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , we say that

truth is τ^b -equationally definable in M , or, more simply, that **truth is τ^b -definable in M** if, for all $\langle \mathcal{A}, T \rangle \in M$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}}.$$

It turns out that classes of algebraic systems forming τ^b -semantics for a π -institution and classes of matrix families in which truth is τ^b -definable are closely interrelated. To express this connection, we first formulate a technical lemma.

Lemma 814 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and let $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ be a set of natural transformations in N^b . Suppose $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, is an $\mathbf{F}$ -matrix family in which truth is τ^b -definable. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,*

$$\phi \in C_\Sigma^{\mathfrak{A}}(\Phi) \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq C^{\mathcal{A}}(\tau_\Sigma^b[\Phi]).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. Then we have the following sequence of equivalent statements:

$$\begin{aligned} \phi \in C_\Sigma^{\mathfrak{A}}(\Phi) & \quad \text{iff, for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma'), \\ & \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq T_{F(\Sigma')} \\ & \quad \quad \quad \text{implies } \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) \in T_{F(\Sigma')} \\ & \quad \text{iff, for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma'), \\ & \quad \tau_{F(\Sigma')}^{\mathcal{A}}[\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi))] \leq \Delta^{\mathcal{A}} \\ & \quad \quad \quad \text{implies } \tau_{F(\Sigma')}^{\mathcal{A}}[\alpha_{\Sigma'}(\text{SEN}^b(f)(\phi))] \leq \Delta^{\mathcal{A}} \\ & \quad \text{iff, for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma'), \\ & \quad \tau_{F(\Sigma')}^{\mathcal{A}}[\text{SEN}(F(f))(\alpha_\Sigma(\Phi))] \leq \Delta^{\mathcal{A}} \\ & \quad \quad \quad \text{implies } \tau_{F(\Sigma')}^{\mathcal{A}}[\text{SEN}(F(f))(\alpha_\Sigma(\phi))] \leq \Delta^{\mathcal{A}} \\ & \quad \text{iff, by Lemma 93,} \\ & \quad \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\Phi)] \leq \Delta^{\mathcal{A}} \text{ implies } \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\phi)] \leq \Delta^{\mathcal{A}} \\ & \quad \text{iff, by surjectivity of } \langle F, \alpha \rangle, \\ & \quad \alpha(\tau_\Sigma^b[\Phi]) \leq \Delta^{\mathcal{A}} \text{ implies } \alpha(\tau_\Sigma^b[\phi]) \leq \Delta^{\mathcal{A}} \\ & \quad \text{iff } \tau_\Sigma^b[\phi] \leq C^{\mathcal{A}}(\tau_\Sigma^b[\Phi]). \end{aligned}$$

■

Now we establish the promised relationship between algebraic semantics and matrix semantics.

Theorem 815 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a set of natural transformation in N^b . A class K of $\mathbf{F}$ -algebraic systems is a τ^b -algebraic semantics for $\mathcal{I}$ if and only if it is the class of underlying algebraic systems of some matrix semantics M for $\mathcal{I}$ in which truth is τ^b -definable.*

Proof: Suppose, first, that M is a matrix semantics for $\mathcal{I}$ in which truth is τ^b -definable and let K be the class of its underlying algebraic systems. Then we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in C_\Sigma(\Phi) & \text{ iff } \phi \in C_\Sigma^M(\Phi) \quad (M \text{ a matrix semantics}) \\ & \text{ iff } (\forall \mathfrak{A} \in M)(\phi \in C_\Sigma^{\mathfrak{A}}(\Phi)) \quad (\text{by definition}) \\ & \text{ iff } (\forall \mathcal{A} \in K)(\tau_\Sigma^b[\phi] \leq C^{\mathcal{A}}(\tau_\Sigma^b[\Phi])) \quad (\text{by Lemma 814}) \\ & \text{ iff } \tau_\Sigma^b[\phi] \leq C^K(\tau_\Sigma^b[\Phi]). \quad (\text{by definition}) \end{aligned}$$

Thus, K is a τ^b -algebraic semantics for $\mathcal{I}$.

Suppose, conversely, that K is a τ^b -algebraic semantics for $\mathcal{I}$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in K$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$. Define, for all $\Sigma \in |\mathbf{Sign}|$,

$$T_\Sigma^{\mathcal{A}, \tau} = \{\phi \in \text{SEN}(\Sigma) : \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}}\},$$

and set $T^{\mathcal{A}, \tau} = \{T_\Sigma^{\mathcal{A}, \tau}\}_{\Sigma \in |\mathbf{Sign}|}$. Then, let

$$M = \{\langle \mathcal{A}, T^{\mathcal{A}, \tau} \rangle : \mathcal{A} \in K\}.$$

Note that K is the class of all underlying algebraic systems of the matrix systems in M and, also, that, for all $\mathcal{A} \in K$, truth is τ^b -definable in $\langle \mathcal{A}, T^{\mathcal{A}, \tau} \rangle$ by the definition of $T^{\mathcal{A}, \tau}$. Thus, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in C_\Sigma(\Phi) & \text{ iff } \tau_\Sigma^b[\phi] \leq C^K(\tau_\Sigma^b[\Phi]) \quad (K \text{ a } \tau^b\text{-semantics}) \\ & \text{ iff } (\forall \mathcal{A} \in K)(\tau_\Sigma^b[\phi] \leq C^{\mathcal{A}}(\tau_\Sigma^b[\Phi])) \quad (\text{by definition}) \\ & \text{ iff } (\forall \mathfrak{A} \in M)(\phi \in C_\Sigma^{\mathfrak{A}}(\Phi)) \quad (\text{by Lemma 814}) \\ & \text{ iff } \phi \in C_\Sigma^M(\Phi). \quad (\text{by definition}) \end{aligned}$$

We conclude that M is a matrix semantics for $\mathcal{I}$. ■

Corollary 816 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution, based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a set of natural transformation in N^b . If truth is τ^b -definable in any of the classes*

$$\text{LMatFam}^*(\mathcal{I}), \text{LMatFam}^{\text{Su}}(\mathcal{I}), \text{MatFam}^*(\mathcal{I}) \text{ or } \text{MatFam}^{\text{Su}}(\mathcal{I}),$$

then, the corresponding class

$$\text{LAlgSys}^*(\mathcal{I}), \text{LAlgSys}^{\text{Su}}(\mathcal{I}), \text{AlgSys}^*(\mathcal{I}) \text{ or } \text{AlgSys}^{\text{Su}}(\mathcal{I})$$

is a τ^b -semantics for $\mathcal{I}$.

Proof: This follows from Theorem 815, since, by Proposition 813, the four displayed classes of $\mathcal{I}$ -matrix families are matrix semantics for $\mathcal{I}$ and the four displayed classes of algebraic systems are, by definition, the respective classes of their underlying algebraic systems. ■

11.6 Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is:

- **Leibniz truth equational** if there exists $\tau^b \subseteq N^b$, with a single distinguished argument, such that truth is τ^b -definable in $\mathbf{LMatFam}^*(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{F}/\Omega(T), T/\Omega(T) \rangle \in \mathbf{LMatFam}^*(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi/\Omega_\Sigma(T) \in T_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)};$$

- **Universally Leibniz truth equational** if there exists $\tau^b \subseteq N^b$, with a single distinguished argument, such that truth is τ^b -definable in the class $\mathbf{MatFam}^*(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{A}, T \rangle \in \mathbf{MatFam}^*(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}};$$

- **Suszko truth equational** if there exists $\tau^b \subseteq N^b$, with a single distinguished argument, such that truth is τ^b -definable in $\mathbf{LMatFam}^{\text{Su}}(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{F}/\tilde{\Omega}^{\mathcal{I}}(T), T/\tilde{\Omega}^{\mathcal{I}}(T) \rangle \in \mathbf{LMatFam}^{\text{Su}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi/\tilde{\Omega}_\Sigma^{\mathcal{I}}(T) \in T_\Sigma/\tilde{\Omega}_\Sigma^{\mathcal{I}}(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\tilde{\Omega}^{\mathcal{I}}(T)}[\phi/\tilde{\Omega}_\Sigma^{\mathcal{I}}(T)] \leq \Delta^{\mathcal{F}/\tilde{\Omega}^{\mathcal{I}}(T)};$$

- **Universally Suszko truth equational** if there exists $\tau^b \subseteq N^b$, with a single distinguished argument, such that truth is τ^b -definable in the class $\mathbf{MatFam}^{\text{Su}}(\mathcal{I})$, i.e., such that, for all $\langle \mathcal{A}, T \rangle \in \mathbf{MatFam}^{\text{Su}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}}.$$

The set $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b will be called a set of **witnessing equations** (of/for the corresponding truth equationality property).

The following proposition provides alternative conditions for testing whether a given π -institution is truth equational with respect to any of the four classes of matrix families considered above.

Proposition 817 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b \subseteq N^b$ having a single distinguished argument.*

- (a) *$\mathcal{I}$ is Leibniz truth equational with witnessing equations τ^b iff, for all $T \in \mathbf{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T);$$

- (b) $\mathcal{I}$ is universally Leibniz truth equational if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, all $T \in \text{FiFam}^{\mathcal{A}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T);$$

- (c) $\mathcal{I}$ is Suszko truth equational with witnessing equations τ^b iff, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T);$$

- (d) $\mathcal{I}$ is universally Suszko truth equational if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, all $T \in \text{FiFam}^{\mathcal{A}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T).$$

Proof:

- (a) Suppose, first, that $\mathcal{I}$ is Leibniz truth equational and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in T_{\Sigma} & \quad \text{iff} \quad \phi/\Omega_{\Sigma}(T) \in T_{\Sigma}/\Omega_{\Sigma}(T) \quad (\text{by compatibility}) \\ & \quad \text{iff} \quad \tau^{\mathcal{F}/\Omega(T)}[\phi/\Omega_{\Sigma}(T)] \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{by definition}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T). \end{aligned}$$

Assume, conversely, that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Let $\langle \mathcal{F}/\Omega(T), T/\Omega(T) \rangle \in \text{LMatFam}^*(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi/\Omega_{\Sigma}(T) \in T_{\Sigma}/\Omega_{\Sigma}(T) & \quad \text{iff} \quad \phi \in T_{\Sigma} \quad (\text{by compatibility}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{by definition}) \\ & \quad \text{iff} \quad \tau^{\mathcal{F}/\Omega(T)}[\phi/\Omega_{\Sigma}(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}. \end{aligned}$$

- (b) Suppose, first, that $\mathcal{I}$ is universally Leibniz truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$. Then

$$\begin{aligned} \phi \in T_{\Sigma} & \quad \text{iff} \quad \phi/\Omega_{\Sigma}^{\mathcal{A}}(T) \in T_{\Sigma}/\Omega_{\Sigma}^{\mathcal{A}}(T) \quad (\text{by compatibility}) \\ & \quad \text{iff} \quad \tau^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}[\phi/\Omega_{\Sigma}^{\mathcal{A}}(T)] \leq \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)} \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi]/\Omega^{\mathcal{A}}(T) \leq \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)} \quad (\text{by definition}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T). \end{aligned}$$

Assume, conversely, that, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T)$. Let $\langle \mathcal{A}, T \rangle \in \text{MatFam}^*(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$. Then

$$\begin{aligned} \phi \in T_{\Sigma} & \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T) \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Delta^{\mathcal{A}}. \quad (\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}) \end{aligned}$$

Parts (c) and (d) follow along similar lines. $\blacksquare$

We investigate next the relationships between the various types of truth equationality. Our first result is that Leibniz truth equationality and universal Leibniz truth equationality coincide.

Proposition 818 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is Leibniz truth equational if and only if it is universally Leibniz truth equational.*

Proof: First, note that, since $\text{LMatFam}^*(\mathcal{I}) \subseteq \text{MatFam}^*(\mathcal{I})$, universal Leibniz truth equationality trivially implies Leibniz truth equationality. Suppose, conversely, that $\mathcal{I}$ is Leibniz truth equational, with witnessing equations $\tau^b \subseteq N^b$. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, we have

$$\begin{aligned} \alpha_{\Sigma}(\phi) \in T_{F(\Sigma)} & \text{ iff } \phi \in \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}) \quad (\text{set theory}) \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \Omega(\alpha^{-1}(T)) \quad (\text{Proposition 817}) \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad (\text{Proposition 24}) \\ & \text{ iff } \alpha(\tau_{\Sigma}^b[\phi]) \leq \Omega^{\mathcal{A}}(T) \quad (\text{set theory}) \\ & \text{ iff } \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_{\Sigma}(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\text{Lemma 96}) \end{aligned}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$ and Proposition 817, we conclude that $\mathcal{I}$ is universally Leibniz truth equational. $\blacksquare$

In the next proposition, we show that (universal) Leibniz truth equationality and universal Suszko truth equationality are also identical properties.

Theorem 819 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is universally Leibniz truth equational if and only if it is universally Suszko truth equational.*

Proof: Since $\text{MatFam}^*(\mathcal{I}) \subseteq \text{MatFam}^{\text{Su}}(\mathcal{I})$, it follows that universal Suszko truth equationality implies universal Leibniz truth equationality. Suppose, conversely, that $\mathcal{I}$ is universally Leibniz truth equational, with witnessing equations τ^b . Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathbf{SEN}(\Sigma)$. By Proposition 817, it suffices to show that

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T).$$

If $\phi \in T_{\Sigma}$, then $\phi \in T'_{\Sigma}$, for all $T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, by hypothesis, $\tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T')$. But then we have

$$\tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \bigcap_{T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})} \Omega^{\mathcal{A}}(T') = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T).$$

Suppose, conversely, that $\tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$. Then, since $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$, we get that $\tau^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T)$, whence, by hypothesis, $\phi \in T_{\Sigma}$.

Using Proposition 817, we conclude that $\mathcal{I}$ is universally Suszko truth equational. ■

Since, for any π -institution $\mathcal{I}$, $\text{LMatFam}^{\text{Su}}(\mathcal{I}) \subseteq \text{MatFam}^{\text{Su}}(\mathcal{I})$, we have, trivially, that universal Suszko truth equationality implies Suszko truth equationality. Therefore, we get the following picture involving implications between the various truth equationality properties:

Next, we present an example of a π -institution $\mathcal{I}$, together with a collection τ^b of natural transformations, with a single distinguished argument, such that truth is τ^b -definable in $\text{LMatFam}^{\text{Su}}(\mathcal{I})$ but not τ^b -definable in $\text{LMatFam}^*(\mathcal{I})$. This shows that, at least in the case in which one considers truth equationality with respect to the same witnessing equations, Suszko truth equationality differs from Leibniz truth equationality.

Example 820 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system defined as follows:

- $\mathbf{Sign}^b$ is the trivial category, with object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is given by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2, 3, 4\}$;
- N^b is the category of natural transformations generated by the four unary natural transformations $\pi^b, \rho^b, \sigma^b, \chi^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by the following table:

$x \in \mathbf{SEN}^b(\Sigma)$	$\pi_{\Sigma}^b(x)$	$\rho_{\Sigma}^b(x)$	$\sigma_{\Sigma}^b(x)$	$\chi_{\Sigma}^b(x)$
0	2	0	3	4
1	2	3	1	4
2	2	3	2	4
3	1	3	4	4
4	2	3	4	4

Define the π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_{\Sigma} = \{\{3, 4\}, \{1, 3, 4\}, \{2, 3, 4\}, \{0, 1, 2, 3, 4\}\}.$$

The lattice of theory families and the corresponding Leibniz congruence systems are shown in the diagram.

All Suszko congruence systems coincide with the corresponding Leibniz congruence systems except for that of the theorem family, for which we have $\tilde{\Omega}^{\mathcal{I}}(\{3, 4\}) = \Delta^{\mathbf{F}}$.

Set $\tau^b = \{\langle \sigma^b, \chi^b \rangle\}$ and compute

$$\begin{aligned} \tau_{\Sigma}^b(0) &= \{\langle 3, 4 \rangle\}, & \tau_{\Sigma}^b(1) &= \{\langle 1, 4 \rangle\}, & \tau_{\Sigma}^b(2) &= \{\langle 2, 4 \rangle\}, \\ \tau_{\Sigma}^b(3) &= \{\langle 4, 4 \rangle\}, & \tau_{\Sigma}^b(4) &= \{\langle 4, 4 \rangle\}. \end{aligned}$$

These calculations enable us to prove that $\mathcal{I}$ is Suszko truth equational with witnessing equations τ^b . The defining equivalence is trivial for $\{0, 1, 2, 3, 4\}$. So we work out the details for the remaining three theory families.

- For the theory family $T = \{\{1, 3, 4\}\}$, we have

$$\begin{aligned} 0 \notin T_{\Sigma} & \quad \text{and} \quad \tau_{\Sigma}^b(0) = \{\langle 3, 4 \rangle\} \notin \tilde{\Omega}_{\Sigma}^{\mathcal{I}}(\{1, 3, 4\}), \\ 1 \in T_{\Sigma} & \quad \text{and} \quad \tau_{\Sigma}^b(1) = \{\langle 1, 4 \rangle\} \subseteq \tilde{\Omega}_{\Sigma}^{\mathcal{I}}(\{1, 3, 4\}), \\ 2 \notin T_{\Sigma} & \quad \text{and} \quad \tau_{\Sigma}^b(2) = \{\langle 2, 4 \rangle\} \notin \tilde{\Omega}_{\Sigma}^{\mathcal{I}}(\{1, 3, 4\}), \\ 3 \in T_{\Sigma} & \quad \text{and} \quad \tau_{\Sigma}^b(3) = \{\langle 4, 4 \rangle\} \subseteq \tilde{\Omega}_{\Sigma}^{\mathcal{I}}(\{1, 3, 4\}), \\ 4 \in T_{\Sigma} & \quad \text{and} \quad \tau_{\Sigma}^b(4) = \{\langle 4, 4 \rangle\} \subseteq \tilde{\Omega}_{\Sigma}^{\mathcal{I}}(\{1, 3, 4\}). \end{aligned}$$

- For the theory family $T = \{\{2, 3, 4\}\}$, we have

$$\begin{aligned}
0 \notin T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(0) = \{\langle 3, 4 \rangle\} \notin \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{2, 3, 4\}), \\
1 \notin T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(1) = \{\langle 1, 4 \rangle\} \notin \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{2, 3, 4\}), \\
2 \in T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(2) = \{\langle 2, 4 \rangle\} \subseteq \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{2, 3, 4\}), \\
3 \in T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(3) = \{\langle 4, 4 \rangle\} \subseteq \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{2, 3, 4\}), \\
4 \in T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(4) = \{\langle 4, 4 \rangle\} \subseteq \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{2, 3, 4\}).
\end{aligned}$$

- Finally, for the theorem family $T = \{\{3, 4\}\}$, we have

$$\begin{aligned}
0 \notin T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(0) = \{\langle 3, 4 \rangle\} \notin \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{3, 4\}), \\
1 \notin T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(1) = \{\langle 1, 4 \rangle\} \notin \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{3, 4\}), \\
2 \notin T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(2) = \{\langle 2, 4 \rangle\} \notin \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{3, 4\}), \\
3 \in T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(3) = \{\langle 4, 4 \rangle\} \subseteq \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{3, 4\}), \\
4 \in T_\Sigma & \quad \text{and} \quad \tau_\Sigma^b(4) = \{\langle 4, 4 \rangle\} \subseteq \widetilde{\Omega}_\Sigma^{\mathcal{I}}(\{3, 4\}).
\end{aligned}$$

So $\mathcal{I}$ is indeed Suszko truth equational with witnessing equations τ^b . On the other hand, τ^b are not witnessing Leibniz truth equationality in $\mathcal{I}$. E.g., we have $\tau_\Sigma^b(0) = \{\langle 3, 4 \rangle\} \subseteq \Omega_\Sigma(\{3, 4\})$, whereas $0 \notin \{3, 4\}$.

We call a π -institution that is (universally) Leibniz truth equational, or equivalently, universally Suszko truth equational, a **family truth-equational π -institution**, or more simply, a **truth equational π -institution**.

Combining these results with Corollary 816, we get the following

Corollary 821 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b . If $\mathcal{I}$ is truth equational with witnessing equations τ^b , then the three classes $\mathbf{LAlgSys}^*(\mathcal{I})$, $\mathbf{AlgSys}^*(\mathcal{I})$ and $\mathbf{AlgSys}^{\text{Su}}(\mathcal{I})$ are τ^b -semantics for $\mathcal{I}$.*

Proof: By the definition of truth equationality, Corollary 816, Proposition 818 and Theorem 819. ■

11.7 More on Truth Equationality

We start this section by looking closely at a property similar to the one defining truth equationality.

Lemma 822 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ a set of natural transformations in N^b . The following statements are equivalent:*

- (a) *For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\tau_\Sigma^b[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi))$;*

(b) For all $T \in \text{ThFam}(\mathcal{I})$, $\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)$.

Proof: For (a) $\Rightarrow$ (b), assume that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\tau_\Sigma^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi))$, and let $T \in \text{ThFam}(\mathcal{I})$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in T_\Sigma$,

$$\begin{aligned} \tau_\Sigma^b[\phi] &\leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)) \quad (\text{hypothesis}) \\ &\leq \tilde{\Omega}^{\mathcal{I}}(T). \quad (\text{monotonicity of } \tilde{\Omega}^{\mathcal{I}}) \end{aligned}$$

Therefore, $\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)$.

For (b) $\Rightarrow$ (a), assume that, for all $T \in \text{ThFam}(\mathcal{I})$, $\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)$, and let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then, by hypothesis,

$$\tau_\Sigma^b[\phi] \leq \tau^b[C(\phi)] \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

■

A very similar property holds replacing theory families by theory systems and using the arrow operators.

Lemma 823 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a set of natural transformations in N^b . The following statements are equivalent:*

(a) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\tau_\Sigma^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi}))$;

(b) For all $T \in \text{ThSys}(\mathcal{I})$, $\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)$.

Proof: For (a) $\Rightarrow$ (b), assume that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\tau_\Sigma^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi}))$, and let $T \in \text{ThSys}(\mathcal{I})$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in T_\Sigma$, $C(\vec{\phi}) \leq T$ and, hence,

$$\begin{aligned} \tau_\Sigma^b[\phi] &\leq \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) \quad (\text{hypothesis}) \\ &\leq \tilde{\Omega}^{\mathcal{I}}(T). \quad (\text{monotonicity of } \tilde{\Omega}^{\mathcal{I}}) \end{aligned}$$

Therefore, $\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)$.

For (b) $\Rightarrow$ (a), assume that, for all $T \in \text{ThSys}(\mathcal{I})$, $\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)$, and let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then, by hypothesis,

$$\tau_\Sigma^b[\phi] \leq \tau^b[C(\vec{\phi})] \leq \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})).$$

■

The property studied in Lemma 822 is one that is satisfied by every π -institution possessing a τ^b -semantics.

Proposition 824 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a set of natural transformations in N^b . If $\mathcal{I}$ has a τ^b -semantics, then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,*

$$\tau_\Sigma^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Suppose that K is a τ^b -semantics for $\mathcal{I}$ and let $\delta^b \approx \epsilon^b$ be an arbitrary equation in τ^b , $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Our goal is to show that, for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \text{SEN}^b(\Sigma')$,

$$\langle \delta_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \epsilon_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}) \rangle \in \tilde{\Omega}_{\Sigma'}^{\mathcal{I}}(C(\phi)).$$

By the characterization theorem for membership in the Suszko congruence system, and using symmetry, it suffices to show that, for all $\sigma^b \in N^b$, all $\Sigma'' \in |\mathbf{Sign}^b|$, all $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma'')$,

$$\begin{array}{ccccc} \Sigma & \xrightarrow{f} & \Sigma' & \xrightarrow{g} & \Sigma'' \\ \phi & \mapsto & \text{SEN}^b(\phi) & \mapsto & \text{SEN}^b(gf)(\phi) \\ & & \vec{\chi} & \mapsto & \text{SEN}^b(g)(\vec{\chi}) \\ & & & & \vec{\xi} \end{array}$$

$$\begin{aligned} & \sigma_{\Sigma''}^b(\text{SEN}^b(g)(\epsilon_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi})), \vec{\xi}) \\ & \in C_{\Sigma''}(\phi, \sigma_{\Sigma''}^b(\text{SEN}^b(g)(\delta_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi})), \vec{\xi})). \end{aligned}$$

This is equivalent to showing

$$\begin{aligned} & \sigma_{\Sigma''}^b(\epsilon_{\Sigma''}^b(\text{SEN}^b(gf)(\phi), \text{SEN}^b(g)(\vec{\chi})), \vec{\xi}) \\ & \in C_{\Sigma''}(\phi, \sigma_{\Sigma''}^b(\delta_{\Sigma''}^b(\text{SEN}^b(gf)(\phi), \text{SEN}^b(g)(\vec{\chi})), \vec{\xi})). \end{aligned}$$

To show this, however, it suffices to show that, for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\sigma_{\Sigma'}^b(\epsilon_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \vec{\xi}) \in C_{\Sigma'}(\phi, \sigma_{\Sigma'}^b(\delta_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \vec{\xi})).$$

This, now, follows from the fact that K is a τ^b -semantics for $\mathcal{I}$ and that, obviously, since $\delta^b \approx \epsilon^b$ is an equation in τ^b ,

$$\begin{aligned} & \tau_{\Sigma'}^b[\sigma_{\Sigma'}^b(\epsilon_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \vec{\xi})] \\ & \leq C^K(\tau_{\Sigma}^b[\phi], \tau_{\Sigma'}^b[\sigma_{\Sigma'}^b(\delta_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \vec{\xi})]). \end{aligned}$$

■

Now we obtain the following consequence:

Corollary 825 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a set of natural transformations in N^b . If $\mathcal{I}$ has a τ^b -algebraic semantics, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\tau^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T).$$

Proof: By Proposition 824 and Lemma 822. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. We say that the Suszko operator:

- is **universally family injective** if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, and all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T') \quad \text{implies} \quad T = T';$$

- has the **universal family minimality** property if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, and every $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$ is the least $\mathcal{I}$ -filter family of $\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$.

Universal family injectivity and universal family minimality of the Suszko operator turn out to be equivalent properties.

Theorem 826 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The Suszko operator is universally family injective if and only if it has the universal family minimality property.*

Proof: Suppose, first, that the Suszko operator has the universal family minimality property. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system and $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T')$. Then both $T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$ and $T'/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T')$ are $\mathcal{I}$ -filter families on the $\mathbf{F}$ -algebraic system $\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T')$. Thus, by the universal family minimality property, $T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = T'/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T')$. Since $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T')$, we get that $T = T'$. So $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}$ is universally family injective.

Suppose, conversely, that the Suszko operator is universally family injective. Consider an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Let T' be the least $\mathcal{I}$ -filter family on $\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$. Since we have $T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \in \text{ThFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T))$, we get, by minimality, that $T' \leq T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$. But then, by the monotonicity of the Suszko operator, we get that

$$\tilde{\Omega}^{\mathcal{I}, \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)}(T') \leq \tilde{\Omega}^{\mathcal{I}, \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)}(T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)) = \Delta^{\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)}$$

and, therefore,

$$\tilde{\Omega}^{\mathcal{I}, \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)}(T') = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)}(T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)) (= \Delta^{\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)}).$$

Hence, by universal family injectivity, $T' = T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$, which proves that the Suszko operator has the universal family minimality property. $\blacksquare$

Finally, recall from Chapter 3, Section 3.8, that a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is called *family c-reflective* if, for every $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$

Also recall that, by the Transfer Theorem ??, $\mathcal{I}$ is family c-reflective if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\mathcal{T} \cup \{T'\} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$

We may call this latter property **universal family complete reflectivity** or **universal family c-reflectivity**.

Our goal, in closing this section is to show that the family injectivity of the Suszko operator (and, hence, by Theorem 826, its universal family minimality) is equivalent to the (universal) family c-reflectivity of $\mathcal{I}$.

We provide, first, an alternative characterization of universal family c-reflectivity involving both the Suszko and the Leibniz congruence systems.

Lemma 827 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is (universally) family c-reflective if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad \text{implies} \quad T \leq T'.$$

Proof: Assume, first, that $\mathcal{I}$ is universally family c-reflective and let $\mathcal{A}$ be an $\mathbf{F}$ -algebraic system and $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Thus, by the definition of the Suszko operator,

$$\bigcap \{ \Omega^{\mathcal{A}}(T'') : T \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \} \leq \Omega^{\mathcal{A}}(T').$$

Using universal family c-reflectivity, we get that

$$\bigcap \{ T'' : T \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \} \leq T'.$$

Hence, $T \leq T'$, as required.

Suppose, conversely, that, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ implies $T \leq T'$. Let $\mathcal{A}$ be an $\mathbf{F}$ -algebraic system and $\mathcal{T} \cup \{T'\} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Then we have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(\bigcap_{T \in \mathcal{T}} T) &\leq \bigcap_{T \in \mathcal{T}} \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \quad (\text{monotonicity of } \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}) \\ &\leq \bigcap_{T \in \mathcal{T}} \Omega^{\mathcal{A}}(T) \quad (\text{since } \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)) \\ &\leq \Omega^{\mathcal{A}}(T'). \quad (\text{by hypothesis}) \end{aligned}$$

Using the hypothesis, we conclude that $\bigcap \mathcal{T} \leq T'$. Therefore, $\mathcal{I}$ is family c-reflective. $\blacksquare$

Finally, we show that family c-reflectivity is identical with the universal family injectivity of the Suszko operator.

Theorem 828 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is (universally) family c-reflective if and only if the Suszko operator is universally family injective.*

Proof: Suppose, first, that the Suszko operator is universally family injective. To show that $\mathcal{I}$ is family c-reflective, we use Lemma 827. Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system and

$T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. This implies that $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$ is compatible with T' . We consider the natural transformation

$$\langle I, \gamma \rangle : \mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T')$$

defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, by

$$\gamma_{\Sigma}(\phi/\tilde{\Omega}_{\Sigma}^{\mathcal{I}, \mathcal{A}}(T)) = \phi/\Omega_{\Sigma}^{\mathcal{A}}(T').$$

Since $T'/\Omega^{\mathcal{A}}(T') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T'))$, we get, by Corollary 55,

$$\gamma^{-1}(T'/\Omega^{\mathcal{A}}(T')) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)),$$

i.e., $T'/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T))$. By universal family injectivity of the Suszko operator and Theorem 826, we get that $T/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq T'/\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$. Taking into account the compatibility of $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T)$ with T' , pointed out above, we get that $T \leq T'$.

Assume, conversely, that $\mathcal{I}$ is (universally) family c-reflective. Let $\mathcal{A}$ be an $\mathbf{F}$ -algebraic system and $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T')$. Then, we have $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$ and $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T') \leq \Omega^{\mathcal{A}}(T)$, whence, by hypothesis and Lemma 827, $T \leq T'$ and $T' \leq T$, showing that $T = T'$. Thus, the Suszko operator is universally family injective. ■

In a nutshell we have the following three equivalent properties, given in Theorems 826 and 828.

11.8 Truth Equationality and c-Reflectivity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Recall from Chapter 3, Section 3.8, that $\mathcal{I}$ is called *family c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

Family c-reflectivity implies family reflectivity, i.e., the property that, for all $T, T' \in \text{ThFam}(\mathcal{I})$, $\Omega(T) \leq \Omega(T')$ implies $T \leq T'$. Finally, family c-reflectivity

is a property strong enough to imply systemicity. Therefore, a π -institution is family c-reflective if and only if it is system c-reflective and systemic.

Recall, also, from Section 11.6, that $\mathcal{I}$ was called (*family*) *truth equational* if it is Leibniz truth equational, that is, if there exists $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that truth is τ^b -definable in $\text{LMatFam}^*(\mathcal{I})$. By Proposition 817, this amounts to the existence of $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

The collection τ^b is termed a **set of witnessing equations** (of/for the truth equationality of $\mathcal{I}$).

Note, again, that truth equationality implies systemicity. In fact, if $\mathcal{I}$ is truth equational with witnessing equations τ^b , then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, we get

$$\begin{aligned} \tau_\Sigma^b[\phi] \leq \Omega(\overleftarrow{T}) & \quad \text{iff} \quad \phi \in \overleftarrow{T}_\Sigma \quad (\text{family truth equationality}) \\ & \text{implies} \quad \phi \in T_\Sigma \quad (\text{Proposition 2}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T) \quad (\text{family truth equationality}) \\ & \text{implies} \quad \tau_\Sigma^b[\phi] \leq \Omega(\overleftarrow{T}). \quad (\text{Proposition 20}) \end{aligned}$$

So all statements above are equivalent showing that $\overleftarrow{T} = T$. Thus, $\mathcal{I}$ is systemic.

It turns out that, if $\mathcal{I}$ is a truth equational π -institution, with witnessing equations τ^b , then $\overleftarrow{\tau^b}(\Omega(T))$ is exactly equal to T , i.e., that the witnessing equations reflect theory families.

Proposition 829 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, with witnessing equations τ^b , then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{\tau^b}(\Omega(T)) = T.$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \overleftarrow{\tau^b}_\Sigma(\Omega(T)) & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T) \quad (\text{definition}) \\ & \quad \text{iff} \quad \phi \in T_\Sigma. \quad (\text{truth equationality}) \end{aligned}$$

■

Proposition 829 has as an immediate consequence the important fact that truth equationality implies family c-reflectivity.

Theorem 830 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, then it is family c-reflective.*

Proof: Suppose that $\mathcal{I}$ is truth equational with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} T &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 829}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis and Lemma 94}) \\ &= T'. \quad (\text{Proposition 829}) \end{aligned}$$

Thus, $\mathcal{I}$ is family c-reflective. ■

The following example shows that, in general, the implication established in Theorem 830 is proper.

Example 831 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the trivial category of natural transformations consisting of the projections only.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, which are also theory systems. Clearly, $\text{Thm}(\mathcal{I}) \leq \mathbf{SEN}^b$. Moreover, $\Omega(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\mathbf{SEN}^b) = \nabla^{\mathbf{F}}$. $\mathcal{I}$ is clearly family c-reflective.

$$\begin{array}{ccc} \mathbf{SEN}^b & \xrightarrow{\quad \cdots \quad} & \nabla^{\mathbf{F}} \\ \downarrow & & \downarrow \\ \text{Thm}(\mathcal{I}) & \xrightarrow{\quad \cdots \quad} & \Delta^{\mathbf{F}} \end{array}$$

On the other hand, there does not exist $\tau^b \subseteq N^b$, such that I^b has the required properties to constitute a witnessing set of equations for the truth equationality in $\mathcal{I}$. Any set consisting of projections only cannot satisfy the required condition since $\overleftarrow{\tau^b}(\Omega(T))$ can only be SEN^b or $\overline{\emptyset}$.

We now work towards a dual goal. We first provide a characterization of truth equationality in terms of the solubility property of the Suszko core of the π -institution. Then, we provide an exact description of those family c-reflective π -institutions which are truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. We define the **Suszko core** $S^{\mathcal{I}}$ of $\mathcal{I}$ to be the collection

$$S^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThFam}(\mathcal{I})) (\sigma^b[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)) \}.$$

By Lemma 822, this definition is equivalent to setting

$$S^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|) (\forall \phi \in \text{SEN}^b(\Sigma)) (\sigma_{\Sigma}^b[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(C(\phi))) \}.$$

The Suszko core has a list of interesting properties.

Proposition 832 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) $\iota \approx \iota \in S^{\mathcal{I}}$, where $\iota : \text{SEN}^b \rightarrow \text{SEN}^b$ denotes the identity;
- (b) If $\delta^b \approx \epsilon^b \in S^{\mathcal{I}}$, then $\epsilon^b \approx \delta^b \in S^{\mathcal{I}}$;
- (c) If $\delta^b \approx \epsilon^b, \epsilon^b \approx \zeta^b \in S^{\mathcal{I}}$, then $\delta^b \approx \zeta^b \in S^{\mathcal{I}}$;
- (d) If $\delta^b \approx \epsilon^b \in S^{\mathcal{I}}$, then, for all $\sigma^b \in N^b$,

$$\sigma^b \circ \langle \delta^b(\vec{p}), \vec{q} \rangle \approx \sigma^b \circ \langle \epsilon^b(\vec{p}), \vec{q} \rangle \in S^{\mathcal{I}},$$

where $\vec{p}, \vec{q}$ denote vectors of projections

$$\vec{p} = \langle p^{k+n-1,0}, \dots, p^{k+n-1,k-1} \rangle, \vec{q} = \langle p^{k+n-1,k}, \dots, p^{k+n-1,k+n-2} \rangle,$$

with k the maximum arity between δ^b and ϵ^b , and n the arity of σ^b .

Proof:

- (a) Since, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in T_{\Sigma}$,

$$(\iota \approx \iota)_{\Sigma}[\phi] \leq \Delta^{\mathbf{F}} \leq \widetilde{\Omega}^{\mathcal{I}}(T),$$

we get, by definition, $\iota \approx \iota \in S^{\mathcal{I}}$.

- (b) Suppose that $\delta^b \approx \epsilon^b \in S^{\mathcal{I}}$. Then, by definition, for all $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in T_\Sigma$, $(\delta^b \approx \epsilon^b)_\Sigma[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T)$. By the symmetry property of the Suszko congruence system $\tilde{\Omega}^{\mathcal{I}}(T)$, we conclude that, for all $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in T_\Sigma$, $(\epsilon^b \approx \delta^b)_\Sigma[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T)$. Therefore, $\epsilon^b \approx \delta^b \in S^{\mathcal{I}}$.
- (c) This follows along the lines of Part (b), using the transitivity of the Suszko congruence system $\tilde{\Omega}^{\mathcal{I}}(T)$ instead of its symmetry.
- (d) Suppose that $\delta^b \approx \epsilon^b \in S^{\mathcal{I}}$ and $\sigma^b \in N^b$. Then, by definition of $S^{\mathcal{I}}$, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in T_\Sigma$, $(\delta^b \approx \epsilon^b)_\Sigma[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T)$. Thus, for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \text{SEN}^b(\Sigma')$,

$$\langle \delta_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \epsilon_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}) \rangle \in \tilde{\Omega}_{\Sigma'}^{\mathcal{I}}(T).$$

But, then, by the congruence compatibility property of $\tilde{\Omega}^{\mathcal{I}}(T)$, we get that, for all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\langle \sigma_{\Sigma'}^b(\delta_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \vec{\xi}), \sigma_{\Sigma'}^b(\epsilon_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \vec{\xi}) \rangle \in \tilde{\Omega}_{\Sigma'}^{\mathcal{I}}(T).$$

Since $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma')$ were arbitrary, we get

$$(\sigma^b \circ \langle \delta^b(\vec{p}), \vec{q} \rangle \approx \sigma^b \circ \langle \epsilon^b(\vec{p}), \vec{q} \rangle)_\Sigma[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T).$$

Finally, since $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in T_\Sigma$ were arbitrary, we conclude that

$$\sigma^b \circ \langle \delta^b(\vec{p}), \vec{q} \rangle \approx \sigma^b \circ \langle \epsilon^b(\vec{p}), \vec{q} \rangle \in S^{\mathcal{I}}. \quad \blacksquare$$

It is clear, by the definitions involved, that the Suszko core of a π -institution satisfies the following property.

Proposition 833 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $T \in \text{ThFam}(\mathcal{I})$,*

$$T \leq \overleftarrow{S}^{\mathcal{I}}(\Omega(T)).$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in T_\Sigma & \text{ implies } S_\Sigma^{\mathcal{I}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) & (\text{definition of } S^{\mathcal{I}}) \\ & \text{ implies } S_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T). & (\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{aligned}$$

Thus, we get that $T \leq \overleftarrow{S}^{\mathcal{I}}(\Omega(T))$. $\blacksquare$

It is possible, but not necessary, that the Suszko core of a π -institution satisfies the reverse inclusion. We call this property *solubility*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the Suszko core of $\mathcal{I}$ is **soluble** if, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\overleftarrow{S^{\mathcal{I}}}(\Omega(T)) \leq T.$$

In other words, $S^{\mathcal{I}}$ is soluble if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_{\Sigma}.$$

We present two examples to showcase the possibilities. In the first example, we look at a π -institution $\mathcal{I}$ whose Suszko core $S^{\mathcal{I}}$ is soluble.

Example 834 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the category of natural transformations generated by the single unary natural transformations $\sigma^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$, specified by setting $\sigma_{\Sigma}^b(x) = 1$, for all $x \in \mathbf{SEN}^b(\Sigma)$.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_{\Sigma} = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, which are also theory systems. Moreover, the structure of the posets of its theory families and of their associated Leibniz congruence systems is given below.

$$\begin{array}{ccc}
 \mathbf{SEN}^b & \xrightarrow{\quad \dots \quad} & \nabla^{\mathbf{F}} \\
 \downarrow & & \downarrow \\
 \text{Thm}(\mathcal{I}) & \xrightarrow{\quad \dots \quad} & \Delta^{\mathbf{F}}
 \end{array}$$

One can see that the Suszko core of $\mathcal{I}$ is given by

$$S^{\mathcal{I}} = \{\iota \approx \iota, \iota \approx \sigma^b, \sigma^b \approx \iota, \sigma^b \approx \sigma^b\}.$$

Since the implication

$$S_{\Sigma}^{\mathcal{I}}[\phi] \leq T \quad \text{implies} \quad \phi \in T_{\Sigma}$$

holds universally, we conclude that the Suszko core of $\mathcal{I}$ is soluble.

Next, we present an example of a π -institution $\mathcal{I}$ whose Suszko core $S^{\mathcal{I}}$ is not soluble.

Example 835 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the trivial category of natural transformations consisting of the projections only.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $C_{\Sigma} = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\mathbf{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, which are also theory systems. Moreover, the structure of the posets of its theory families and of their associated Leibniz congruence systems is given below.

$$\begin{array}{ccc} \mathbf{SEN}^b & \xrightarrow{\quad \quad \quad} & \nabla^{\mathbf{F}} \\ \downarrow & & \downarrow \\ \mathbf{Thm}(\mathcal{I}) & \xrightarrow{\quad \quad \quad} & \Delta^{\mathbf{F}} \end{array}$$

One can see that the Suszko core of $\mathcal{I}$ is given by

$$S^{\mathcal{I}} = \{\iota \approx \iota\}.$$

We, thus, have that

$$S_{\Sigma}^{\mathcal{I}}[0] \leq \Delta^{\mathbf{F}} = \Omega(\text{Thm}(\mathcal{I})) \quad \text{but} \quad 0 \notin \text{Thm}_{\Sigma}(\mathcal{I}).$$

Therefore, $S^{\mathcal{I}}$ is not soluble.

It turns out that possession of the solubility property by the Suszko core intrinsically characterizes truth equationality. We can show, at the outset, that the Suszko core being soluble is necessary for truth equationality. Thus, there is no point in trying to discover witnessing equations unless the Suszko core of the π -institution $\mathcal{I}$ under scrutiny is soluble.

To show this, observe, first, that, in case a π -institution is truth equational, the witnessing equations form a subset of the Suszko core.

Lemma 836 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, with witnessing equations $\tau^b \subseteq N^b$, then $\tau^b \subseteq S^{\mathcal{I}}$.*

Proof: By truth equationality, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T).$$

Thus, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in T_{\Sigma} & \quad \text{iff} \quad (\forall T \leq T' \in \text{ThFam}(\mathcal{I}))(\phi \in T'_{\Sigma}) \\ & \quad \text{iff} \quad (\forall T \leq T' \in \text{ThFam}(\mathcal{I}))(\tau_{\Sigma}^b[\phi] \leq \Omega(T')) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \bigcap \{ \Omega(T') : T \leq T' \in \text{ThFam}(\mathcal{I}) \} \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T). \end{aligned}$$

We conclude, by the definition of $S^{\mathcal{I}}$, that $\tau^b \subseteq S^{\mathcal{I}}$. ■

Now we prove the necessity of solubility for truth equationality.

Theorem 837 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, then $S^{\mathcal{I}}$ is soluble.*

Proof: Suppose that $\mathcal{I}$ is truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) & \quad \text{implies} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{Lemma 836}) \\ & \quad \text{iff} \quad \phi \in T_{\Sigma}. \quad (\text{truth equationality}) \end{aligned}$$

Thus, $S^{\mathcal{I}}$ is soluble. ■

The reverse implication, which also holds and completes the promised characterization of truth equationality in terms of the Suszko core, is presented in the following result.

Theorem 838 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^\mathcal{I}$ is soluble, then $\mathcal{I}$ is truth equational, with witnessing equations $S^\mathcal{I}$.*

Proof: It suffices to show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad S^\mathcal{I}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 833, whereas the converse is ensured by the postulated solubility of $S^\mathcal{I}$. ■

Theorems 837 and 838 provide the promised characterization of truth equationality in terms of the solubility of the Suszko core.

$$\mathcal{I} \text{ is Truth Equational} \longleftrightarrow S^\mathcal{I} \text{ is Soluble.}$$

Theorem 839 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if $S^\mathcal{I}$ is soluble.*

Proof: Theorem 837 gives the “only if” and the “if” is by Theorem 838. ■

If $\mathcal{I}$ is truth equational, then the Suszko core defines theory families in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 829, since $S^\mathcal{I}$ forms a maximal set of witnessing equations for the truth equationality of $\mathcal{I}$.

Proposition 840 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^\mathcal{I}$ is soluble, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$T = \overleftarrow{S^\mathcal{I}}(\Omega(T)).$$

Proof: If $S^\mathcal{I}$ is soluble, then, by Theorem 838, $S^\mathcal{I}$ forms a set of witnessing equations for the truth equationality of $\mathcal{I}$. Therefore, by Proposition 829, we get that, for every $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{S^\mathcal{I}}(\Omega(T))$. ■

In fact, this property may also be restated as another characterization of truth equationality. Let us say that $S^\mathcal{I}$ **defines theory families** if, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{S^\mathcal{I}}(\Omega(T))$. Then we have:

$$\mathcal{I} \text{ is Truth Equational} \longleftrightarrow S^\mathcal{I} \text{ Defines Theory Families.}$$

Theorem 841 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$T = \overleftarrow{S^\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is truth equational, then, by Theorem 839, $S^{\mathcal{I}}$ is soluble. Thus, by Proposition 840, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{S}^{\mathcal{I}}(\Omega(T))$.

Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{S}^{\mathcal{I}}(\Omega(T))$, then $S^{\mathcal{I}}$ is soluble. Thus, again by Theorem 839, $S^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is truth equational. ■

We finally show that the property that separates family complete reflectivity from truth equationality is exactly the *adequacy* property of the Suszko core. Roughly speaking, this property ensures that the Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

We have the following relationship connecting the Suszko core with both Leibniz and Suszko congruence systems.

Proposition 842 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\begin{aligned} \phi \in T_{\Sigma} & \text{ implies } S_{\Sigma}^{\mathcal{I}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \quad (\text{definition of the Suszko core}) \\ & \text{ implies } S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T). \quad (\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{aligned}$$

Therefore, we have

$$\begin{aligned} \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} & \leq \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \} \\ & \leq \bigcap \{ \Omega(T) : \phi \in T_{\Sigma} \} \\ & = \tilde{\Omega}^{\mathcal{I}}(C(\phi)). \end{aligned}$$

■

We provide an example, next, that shows that the inclusion proven in Proposition 842 is proper, in general. I.e., there exist π -institutions $\mathcal{I}$ in which, for some signature Σ and some Σ -sentence ϕ ,

$$\bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \not\leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Example 843 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the trivial category with object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the trivial category of natural transformations, consisting of the projections only.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and SEN^b , all of which are theory systems.

Note that $S^\mathcal{I} = \{\iota \approx \iota\}$. Note, also, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems, that are provided in the left and right sides, respectively, of the following diagram, where

$$T = \{\{1, 2\}\}, \quad \theta = \{\{0\}, \{1, 2\}\}, \quad \theta' = \{\{0, 1\}, \{2\}\}.$$

Taking this into account, it is not difficult to see that

$$\bigcap \{\Omega(T) : S_\Sigma^\mathcal{I}[1] \leq \Omega(T)\} = \Delta^\mathbf{F} \not\leq \theta = \tilde{\Omega}^\mathcal{I}(C(1)).$$

We also give an example of a π -institution $\mathcal{I}$ whose Suszko core $S^\mathcal{I}$ is such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^\mathcal{I}(C(\phi)) = \bigcap \{\Omega(T) : S_\Sigma^\mathcal{I}[\phi] \leq \Omega(T)\}.$$

Example 844 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with object Σ ;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$;

- N^b is the category of natural transformations generated by the single unary natural transformation $\sigma^b : \text{SEN}^b \rightarrow \text{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given, for all $x \in \text{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x) = 2.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and SEN^b , all of which are theory systems.

Note that $S^\mathcal{I} = \{\iota \approx \iota, \iota \approx \sigma^b, \sigma^b \approx \iota, \sigma^b \approx \sigma^b\}$. Note, also, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems, that are provided in the left and right sides, respectively, of the following diagram, where

$$T = \{\{1, 2\}\}, \quad \theta = \{\{0\}, \{1, 2\}\}, \quad \theta' = \{\{0, 1\}, \{2\}\}.$$

Now we can check:

$$\begin{aligned} \tilde{\Omega}^\mathcal{I}(C(0)) &= \nabla^\mathbf{F} = \Omega(\text{SEN}^b) \\ &= \cap \{\Omega(T) : S_\Sigma^\mathcal{I}[0] \leq \Omega(T)\}; \\ \tilde{\Omega}^\mathcal{I}(C(1)) &= \theta = \Omega(\text{SEN}^b) \cap \Omega(T) \\ &= \cap \{\Omega(T) : S_\Sigma^\mathcal{I}[1] \leq \Omega(T)\}; \\ \tilde{\Omega}^\mathcal{I}(C(2)) &= \Delta^\mathbf{F} = \Omega(\text{SEN}^b) \cap \Omega(T) \cap \Omega(\text{Thm}(\mathcal{I})) \\ &= \cap \{\Omega(T) : S_\Sigma^\mathcal{I}[2] \leq \Omega(T)\}. \end{aligned}$$

We have seen, therefore, through examples, that it is possible, but not necessary, that the Suszko core of a π -institution satisfies, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, the reverse inclusion of that given in Proposition 842:

$$\tilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Intuitively speaking, this means that the Suszko core $S^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and every Σ -sentence ϕ , the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\phi)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. We say that the Suszko core $S^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Based on our preceding work, it is not difficult to see that, if $S^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 845 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(C(\phi)) &= \bigcap \{ \Omega(T) : \phi \in T_{\Sigma} \} \quad (\text{definition of } \tilde{\Omega}^{\mathcal{I}}(C(\phi))) \\ &= \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \\ &\quad (\text{solubility of } S^{\mathcal{I}} \text{ and Proposition 840}) \end{aligned}$$

We conclude that $S^{\mathcal{I}}$ is adequate. ■

Here is an example of a π -institution $\mathcal{I}$, with an adequate but not soluble Suszko core.

Example 846 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = i_{\Sigma}$;
- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\text{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 1$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the trivial category of natural transformations (consisting of the projections only).

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has four theory families $\text{Thm}(\mathcal{I})$, $T = \{\{0, 2\}\}$, $T' = \{\{1, 2\}\}$ and SEN^b , but only two theory systems $\text{Thm}(\mathcal{I})$ and SEN^b . Therefore, being non-systemic, it can be neither family c -reflective nor truth-equational. The fact that it is not truth equational, together with Theorem 839, reveal that the Suszko core $S^\mathcal{I}$ is not soluble.

To verify that $S^\mathcal{I}$ is adequate, we look at the posets of theory families (left), Leibniz congruence systems (right) and Suszko congruence systems (right, identical with the Leibniz congruence systems, since the π -institution is protoalgebraic).

Since $S^\mathcal{I} = \{\iota \approx \iota\}$, we verify adequacy of $S^\mathcal{I}$ by the following calculation, holding for all $\phi \in \text{SEN}^b(\Sigma)$:

$$\tilde{\Omega}^\mathcal{I}(C(\phi)) = \Delta^\mathbf{F} = \bigcap_{T \in \text{ThFam}(\mathcal{I})} \Omega(T) = \bigcap \{\Omega(T) : S_\Sigma^\mathcal{I}[\phi] \leq \Omega(T)\}.$$

Thus, $S^\mathcal{I}$ is in fact adequate but not soluble.

In the opposite direction, and on the positive side, in a family c -reflective π -institution $\mathcal{I}$, if the Suszko core is adequate, then it is also soluble.

Proposition 847 Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a family c -reflective π -institution based on $\mathbf{F}$. If $S^\mathcal{I}$ is adequate, then it is soluble.

Proof: Suppose that $\mathcal{I}$ is family c-reflective and that $S^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 833. For the converse, assume that $S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by the adequacy of $S^{\mathcal{I}}$, we get that $\tilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \Omega(T)$. Thus, by family c-reflectivity and Lemma 827, we conclude that $C(\phi) \leq T$, which gives $\phi \in T_{\Sigma}$. ■

We finally show that a π -institution is truth equational if and only if it is family c-reflective and has an adequate Suszko core.

$$\begin{aligned} \text{Truth Equationality} &= S^{\mathcal{I}} \text{ Soluble} \\ &= S^{\mathcal{I}} \text{ Defines Theory Families} \\ &= \text{Family c-Reflectivity} + S^{\mathcal{I}} \text{ Adequate} \end{aligned}$$

Theorem 848 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if it is family c-reflective and has an adequate Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is truth equational. Then it is family c-reflective by Theorem 830. Moreover, its Suszko core is soluble by Theorem 839 and, hence, by Corollary 845, its Suszko core is adequate.

Suppose, conversely, that $\mathcal{I}$ is family c-reflective with an adequate Suszko core. Then, by Proposition 847, its Suszko core is soluble and, therefore, by Theorem 839, $\mathcal{I}$ is truth equational. ■

Finally, it is not difficult to see that, in some sense, truth equationality transfers from a π -institution to all $\mathcal{I}$ -matrix families.

Theorem 849 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational, with witnessing transformations $\tau^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ in N^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T = \overleftarrow{\tau}^{\mathcal{A}}(\Omega^{\mathcal{A}}(T))$.*

Proof: Suppose $\mathcal{I}$ is truth equational, with witnessing transformations $\tau^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, whence, by hypothesis, $\alpha^{-1}(T) = \overleftarrow{\tau}^b(\Omega(\alpha^{-1}(T)))$. Hence, by Proposition 24, $\alpha^{-1}(T) = \overleftarrow{\tau}^b(\alpha^{-1}(\Omega^{\mathcal{A}}(T)))$. Therefore, for all $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, we get

$$\begin{aligned} \alpha_{\Sigma}(\phi) \in T_{F(\Sigma)} &\quad \text{iff} \quad \phi \in \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}) \\ &\quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \\ &\quad \text{iff} \quad \alpha(\tau_{\Sigma}^b[\phi]) \leq \Omega^{\mathcal{A}}(T) \\ &\quad \text{iff} \quad \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_{\Sigma}(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\langle F, \alpha \rangle \text{ surjective}) \end{aligned}$$

Taking again into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, $\phi \in T_\Sigma$ if and only if $\tau_\Sigma^A[\phi] \leq \Omega^A(T)$, i.e., $T = \overleftarrow{\tau^A}(\Omega^A(T))$. ■

11.9 Left Truth Equationality

In this section, we look at versions of truth equationality and c-reflectivity that can still be applied to general theory families but do not force the π -institutions to be systemic. In the next section we will also look at *system truth equationality*, i.e., truth equationality applied only to theory systems, and at *system c-reflectivity*. In this section we take the “leftist” approach, “left” having the meaning attributed to it in Chapter 3.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 3, Section 3.8, that $\mathcal{I}$ is *left c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}.$$

Left c-reflectivity is not strong enough to imply systemicity. Moreover, left c-reflectivity is a property intermediate between family c-reflectivity and system c-reflectivity.

We say that the π -institution $\mathcal{I}$ is **left truth equational** if there exists $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

In that case, we call τ^b a **set of witnessing equations** (of/for the left truth equationality of $\mathcal{I}$).

If $\mathcal{I}$ is a left truth equational π -institution, with witnessing equations τ^b , then $\tau^b(\Omega(T))$ is exactly equal to $\overleftarrow{T}$, i.e., the witnessing equations reflect theory families only “up to arrow”.

Proposition 850 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, with witnessing equations τ^b , then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{\tau^b}(\Omega(T)) = \overleftarrow{T}.$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \overleftarrow{\tau^b}(\Omega(T)) &\quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T) \quad (\text{definition}) \\ &\quad \text{iff} \quad \phi \in \overleftarrow{T}_\Sigma. \quad (\text{left truth equationality}) \end{aligned} \quad \blacksquare$$

Proposition 850 has as an immediate consequence the important fact that left truth equationality implies left c-reflectivity.

Theorem 851 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, then it is left c-reflective.*

Proof: Suppose that $\mathcal{I}$ is left truth equational with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} \overleftarrow{T} &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 850}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis and Lemma 94}) \\ &= \overleftarrow{T'}. \quad (\text{Proposition 850}) \end{aligned}$$

Thus, $\mathcal{I}$ is left c-reflective. ■

The following example shows that the implication of Theorem 851 is strict.

Example 852 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the trivial category of natural transformations consisting of the projections only.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, which are also theory systems. In other words, $\overleftarrow{\text{Thm}(\mathcal{I})} = \text{Thm}(\mathcal{I})$ and $\overleftarrow{\mathbf{SEN}^b} = \mathbf{SEN}^b$. Clearly,

$\text{Thm}(\mathcal{I}) \leq \text{SEN}^b$. Moreover, $\Omega(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\text{SEN}^b) = \nabla^{\mathbf{F}}$. $\mathcal{I}$ is clearly left c-reflective.

$$\begin{array}{ccc} \text{SEN}^b & \xrightarrow{\quad \quad \quad} & \nabla^{\mathbf{F}} \\ \downarrow & & \downarrow \\ \text{Thm}(\mathcal{I}) & \xrightarrow{\quad \quad \quad} & \Delta^{\mathbf{F}} \end{array}$$

On the other hand, there does not exist $\tau^b \subseteq N^b$, such that I^b has the required properties to constitute a witnessing set of equations for the left truth equationality in $\mathcal{I}$. Any set consisting of projections only cannot satisfy the required condition since $\overleftarrow{\tau^b}(\Omega(T))$ can only be SEN^b or $\overline{\emptyset}$.

We provide, next, a characterization of left truth equationality in terms of the left solubility property of the left Suszko core of the π -institution. Then, we provide an exact description of those left c-reflective π -institutions which are left truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **left Suszko core** of $\mathcal{I}$ is the collection

$$L^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThFam}(\mathcal{I})) (\sigma^b[\overleftarrow{T}] \leq \widetilde{\Omega}^{\mathcal{I}}(T)) \}.$$

There is an alternative way to define the left Suszko core of a π -institution, which may also be viewed as justifying the alternative terminology *system Suszko core* for it, which we state in the form of a property.

Proposition 853 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$L^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)) \}.$$

Proof: Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution and set

$$M^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T)) \}.$$

Our goal is to show that $M^{\mathcal{I}} = L^{\mathcal{I}}$.

Suppose, first, that $\sigma^b \in L^{\mathcal{I}}$ and let $T \in \text{ThSys}(\mathcal{I})$. Then, we have

$$\begin{aligned} \sigma^b[T] &= \sigma^b[\overleftarrow{\overleftarrow{T}}] \quad (T \in \text{ThSys}(\mathcal{I})) \\ &\leq \widetilde{\Omega}^{\mathcal{I}}(T). \quad (\sigma^b \in L^{\mathcal{I}}) \end{aligned}$$

Therefore $\sigma^b \in M^{\mathcal{I}}$.

Suppose, conversely, that $\sigma^b \in M^{\mathcal{I}}$ and let $T \in \text{ThFam}(\mathcal{I})$. Then, we have

$$\begin{aligned} \sigma^b[\overleftarrow{\overleftarrow{T}}] &\leq \widetilde{\Omega}^{\mathcal{I}}(\overleftarrow{\overleftarrow{T}}) \quad (\sigma^b \in M^{\mathcal{I}} \text{ and } \overleftarrow{\overleftarrow{T}} \in \text{ThSys}(\mathcal{I})) \\ &\leq \widetilde{\Omega}^{\mathcal{I}}(T). \quad (\overleftarrow{\overleftarrow{T}} \leq T \text{ and monotonicity of } \widetilde{\Omega}^{\mathcal{I}}) \end{aligned}$$

We conclude that $\sigma^b \in L^{\mathcal{I}}$ and, therefore, $M^{\mathcal{I}} = L^{\mathcal{I}}$. ■

Note that, since, for every $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} \leq T$, we get that $S^{\mathcal{I}} \subseteq L^{\mathcal{I}}$, which implies that, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{L^{\mathcal{I}}}(\Omega(T)) \leq \overleftarrow{S^{\mathcal{I}}}(\Omega(T))$. Note, also, that for systemic π -institutions the left Suszko core and the Suszko core are identical.

The left Suszko core of a π -institution satisfies the following property relating to the arrow operator.

Proposition 854 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} \leq L^{\mathcal{I}}(\Omega(T)).$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in \overleftarrow{T}_{\Sigma} & \text{ implies } L_{\Sigma}^{\mathcal{I}}[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T) \quad (\text{by definition of } L^{\mathcal{I}}) \\ & \text{ implies } L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\ & \text{ iff } \phi \in \overleftarrow{L^{\mathcal{I}}}(\Omega(T)). \quad (\text{by definition}) \end{aligned}$$
■

It is possible, but not necessary, that the left Suszko core of a π -institution satisfies the reverse inclusion. We call this property left solubility.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the left Suszko core of $\mathcal{I}$ is **left soluble** if, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\overleftarrow{L^{\mathcal{I}}}(\Omega(T)) \leq \overleftarrow{T}.$$

In other words, $L^{\mathcal{I}}$ is left soluble if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \overleftarrow{T}_{\Sigma}.$$

We show that this property has an alternative characterization in terms of theory systems.

Proposition 855 *Let $\mathcal{I} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is left soluble if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{L^{\mathcal{I}}}(\Omega(T)) = T$.*

Proof: For the “only if”, assume that $L^{\mathcal{I}}$ is left soluble and let $T \in \text{ThSys}(\mathcal{I})$. Then

$$\begin{aligned} \overleftarrow{L^{\mathcal{I}}}(\Omega(T)) &= \overleftarrow{T} \quad (\text{Left Solubility of } L^{\mathcal{I}}) \\ &= T. \quad (T \in \text{ThSys}(\mathcal{I})) \end{aligned}$$

Conversely, assume that, for all $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{L}^{\mathcal{I}}(\Omega(T)) = T$ and let $T \in \text{ThFam}(\mathcal{I})$. Then, we have

$$\begin{aligned} \overleftarrow{L}^{\mathcal{I}}(\Omega(T)) &\leq \overleftarrow{L}^{\mathcal{I}}(\Omega(\overleftarrow{T})) \quad (\text{Proposition 20 and Lemma 94}) \\ &= \overleftarrow{T}. \quad (\text{by hypothesis}) \end{aligned}$$

Thus, $L^{\mathcal{I}}$ is left soluble. ■

Note that for systemic π -institutions, since the left Suszko core coincides with the Suszko core, left solubility of the left Suszko core coincides with the solubility of the Suszko core. These two properties are, however, different in general and, as the following proposition and example show, solubility of the Suszko core is a stronger property than left solubility of the left Suszko core.

Proposition 856 *Let $\mathcal{I} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If the Suszko core $S^{\mathcal{I}}$ of $\mathcal{I}$ is soluble, then the left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is left soluble.*

Proof: Suppose that $S^{\mathcal{I}}$ is soluble, i.e., for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_{\Sigma}.$$

Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, since $S^{\mathcal{I}} \subseteq L^{\mathcal{I}}$ (see remark after Proposition 853), we get that $S^{\mathcal{I}}[\phi] \leq \Omega(T)$. Moreover, since, by Proposition 20, $\Omega(T) \leq \Omega(\overleftarrow{T})$, we get that $S^{\mathcal{I}}[\phi] \leq \Omega(\overleftarrow{T})$. Thus, by the solubility of $S^{\mathcal{I}}$, we get that $\phi \in \overleftarrow{T}_{\Sigma}$. We conclude that $L^{\mathcal{I}}$ is left soluble. ■

The implication of Proposition 856 is proper in general.

Example 857 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the category with single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$ and $\mathbf{SEN}^b(f) : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ given by $0 \mapsto 0$, $1 \mapsto 0$ and $2 \mapsto 2$;
- N^b is the category of natural transformations generated by the single unary natural transformation $\sigma^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_{\Sigma}^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given, for all $x \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_{\Sigma}^b(x) = 2.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and SEN^b , but only two theory systems $\text{Thm}(\mathcal{I})$ and SEN^b . So it is not a systemic π -institution.

The posets of theory families and associated Leibniz congruence systems are shown in the following figure (where $T \in \{\{1, 2\}\}$ and $\theta = \{\{0, 1\}, \{2\}\}$):

Note that

$$S^{\mathcal{I}} = \{\iota \approx \iota, \sigma^b \approx \sigma^b\},$$

whereas

$$L^{\mathcal{I}} = \{\iota \approx \iota, \iota \approx \sigma^b, \sigma^b \approx \iota, \sigma^b \approx \sigma^b\}.$$

We show that $L^{\mathcal{I}}$ is left soluble, but that $S^{\mathcal{I}}$ is not soluble.

The left solubility of $L^{\mathcal{I}}$ can be seen by looking at the defining implication on a case-by-case basis. The case of the theory family SEN^b is trivial as is the case for $\phi = 2$. For $\phi = 0$ or 1 and for the theory families T or $\text{Thm}(\mathcal{I})$, we have:

- $L_\Sigma^{\mathcal{I}}[0] \leq \Omega(T)$ is false;
- $L_\Sigma^{\mathcal{I}}[1] \leq \Omega(T)$ is false;
- $L_\Sigma^{\mathcal{I}}[0] \leq \Omega(\text{Thm}(\mathcal{I}))$ is false;
- $L_\Sigma^{\mathcal{I}}[1] \leq \Omega(\text{Thm}(\mathcal{I}))$ is false.

So in every other case the defining condition is vacuously satisfied.

On the other hand, $S_{\Sigma}^{\mathcal{I}}[0] \leq \Omega(T)$, but $0 \notin T_{\Sigma}$, which shows that $S^{\mathcal{I}}$ is not soluble.

It turns out that possession of left solubility by the left Suszko core intrinsically characterizes left truth equationality. We show, first, that the left Suszko core being left soluble is necessary for left truth equationality. To demonstrate this, observe, first, that, in case a π -institution is left truth equational, the witnessing equations form a subset of the left Suszko core.

Lemma 858 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, with witnessing equations $\tau^b \subseteq N^b$, then $\tau^b \subseteq L^{\mathcal{I}}$.*

Proof: By left truth equationality, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T).$$

Thus, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \overleftarrow{T}_{\Sigma} & \quad \text{iff} \quad (\forall T \leq T' \in \text{ThFam}(\mathcal{I}))(\phi \in \overleftarrow{T'}_{\Sigma}) \\ & \quad \text{(by Lemma 1)} \\ & \quad \text{iff} \quad (\forall T \leq T' \in \text{ThFam}(\mathcal{I}))(\tau_{\Sigma}^b[\phi] \leq \Omega(T')) \\ & \quad \quad \text{(left truth equationality; displayed formula above)} \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \bigcap \{ \Omega(T') : T \leq T' \in \text{ThFam}(\mathcal{I}) \} \\ & \quad \quad \text{(set theoretically)} \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T). \quad \text{(by definition of } \widetilde{\Omega}^{\mathcal{I}} \text{)} \end{aligned}$$

We conclude, by the definition of $L^{\mathcal{I}}$, that $\tau^b \subseteq L^{\mathcal{I}}$. ■

Now we prove the necessity of left solubility of the left Suszko core for left truth equationality.

Theorem 859 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is left truth equational, then $L^{\mathcal{I}}$ is left soluble.*

Proof: Suppose that $\mathcal{I}$ is left truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) & \quad \text{implies} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad \text{(Lemma 858)} \\ & \quad \text{iff} \quad \phi \in \overleftarrow{T}_{\Sigma}. \quad \text{(left truth equationality)} \end{aligned}$$

Thus, $L^{\mathcal{I}}$ is left soluble. ■

The reverse implication also holds and completes the promised characterization of left truth equationality in terms of the left Suszko core.

Theorem 860 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $L^\mathcal{I}$ is left soluble, then $\mathcal{I}$ is left truth equational, with witnessing equations $L^\mathcal{I}$.*

Proof: It suffices to show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad L^\mathcal{I}_\Sigma[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 854, whereas the converse is ensured by the postulated left solubility of $L^\mathcal{I}$. $\blacksquare$

Theorems 859 and 860 provide the promised characterization of left truth equationality in terms of the left solubility of the left Suszko core.

$$\mathcal{I} \text{ is Left Truth Equational} \longleftrightarrow L^\mathcal{I} \text{ is Left Soluble.}$$

Theorem 861 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if $L^\mathcal{I}$ is left soluble.*

Proof: Theorem 859 gives the “only if” and the “if” is by Theorem 860. $\blacksquare$

If $\mathcal{I}$ is left truth equational, then the left Suszko core defines theory families in $\mathcal{I}$ “up to arrow” in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 850, since $L^\mathcal{I}$ forms a maximal set of witnessing equations of the left truth equationality of $\mathcal{I}$.

Proposition 862 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $L^\mathcal{I}$ is left soluble, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} = \overleftarrow{L^\mathcal{I}}(\Omega(T)).$$

Proof: If $L^\mathcal{I}$ is left soluble, then, by Theorem 860, $L^\mathcal{I}$ forms a set of witnessing equations for the left truth equationality of $\mathcal{I}$. Therefore, by Proposition 850, we get that, for every $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^\mathcal{I}}(\Omega(T))$. $\blacksquare$

This property may be restated as another characterization of left truth equationality. We say that $L^\mathcal{I}$ **defines theory families up to arrow** if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^\mathcal{I}}(\Omega(T))$. Then we have:

$$\begin{aligned} \mathcal{I} \text{ is Left Truth Equational} \\ \longleftrightarrow L^\mathcal{I} \text{ Defines Theory Families Up to Arrow.} \end{aligned}$$

Theorem 863 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} = \overleftarrow{L^\mathcal{I}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is left truth equational, then, by Theorem 861, $L^{\mathcal{I}}$ is left soluble. Thus, by Proposition 862, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^{\mathcal{I}}}(\Omega(T))$.

Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^{\mathcal{I}}}(\Omega(T))$, then, $L^{\mathcal{I}}$ is left soluble. Thus, again by Theorem 861, $L^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is left truth equational. ■

We finally show that the property that separates left complete reflectivity from left truth equationality is a property of the left Suszko core, analogous to the adequacy property introduced previously for the Suszko core, that we call *left adequacy*. Informally speaking, similarly to adequacy, this property ensures that the left Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

The following relationship connects the left Suszko core with both Leibniz and Suszko congruence systems.

Recall from Section 2.2 of Chapter 2 that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$, and a sentence family $T \in \text{SenFam}(\mathcal{I})$, we denote by $\overrightarrow{T}$ the least sentence system of $\mathcal{I}$ that includes T .

Proposition 864 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,*

$$\cap\{\Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\} \leq \tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\begin{aligned} \phi \in \overleftarrow{T}_{\Sigma} & \text{ implies } L_{\Sigma}^{\mathcal{I}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \quad (\text{definition of the left Suszko core}) \\ & \text{ implies } L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T). \quad (\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{aligned}$$

Therefore, we have

$$\begin{aligned} \cap\{\Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\} & \leq \cap\{\Omega(T) : \phi \in \overleftarrow{T}_{\Sigma}\} \\ & = \cap\{\Omega(T) : \overrightarrow{\phi} \leq T\} \\ & = \tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})). \end{aligned}$$

We provide an example, next, that shows that the inclusion proven in Proposition 864 is proper, in general. I.e., there exist π -institutions $\mathcal{I}$ in which, for some signature Σ and some Σ -sentence ϕ ,

$$\cap\{\Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\} \not\leq \tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

Of course, it is convenient that, in a systemic π -institution, $L^{\mathcal{I}} = S^{\mathcal{I}}$ and, moreover, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $C(\overrightarrow{\phi}) = C(\phi)$, whence Example 843, used to prove proper inclusion following Proposition 842, may be reused.

Example 865 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the trivial category of natural transformations, consisting of the projections only.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{\{1, 2\}\}$ and $\mathbf{SEN}^b$, all of which are theory systems. So $\mathcal{I}$ is systemic.

We have $L^\mathcal{I} = S^\mathcal{I} = \{\iota \approx \iota\}$. Furthermore, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems are provided in the left and right sides, respectively, of the diagram, where

$$T = \{\{1, 2\}\}, \quad \theta = \{\{0\}, \{1, 2\}\}, \quad \theta' = \{\{0, 1\}, \{2\}\}.$$

Taking this into account, it is not difficult to see that

$$\bigcap \{\Omega(T) : L_\Sigma^\mathcal{I}[1] \leq \Omega(T)\} = \Delta^\mathbf{F} \not\leq \theta = \tilde{\Omega}^\mathcal{I}(C(1)) = \tilde{\Omega}^\mathcal{I}(C(\vec{1})).$$

We also give an example of a π -institution $\mathcal{I}$ whose left Suszko core $L^{\mathcal{I}}$ is such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) = \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

This again takes after Example 844, since the π -institution used there was systemic.

Example 866 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the category of natural transformations generated by the single unary natural transformation $\sigma^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_{\Sigma}^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given, for all $x \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_{\Sigma}^b(x) = 2.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_{\Sigma} = \{ \{2\}, \{1, 2\}, \{0, 1, 2\} \}.$$

$\mathcal{I}$ has three theory families $\text{Thm}(\mathcal{I})$, $T = \{ \{1, 2\} \}$ and $\mathbf{SEN}^b$, all of which are theory systems. So $\mathcal{I}$ is systemic.

Note that $L^{\mathcal{I}} = S^{\mathcal{I}} = \{ \iota \approx \iota, \iota \approx \sigma^b, \sigma^b \approx \iota, \sigma^b \approx \sigma^b \}$. Note, also, the structure of the posets of Leibniz congruence systems and of Suszko congruence systems, that are provided in the left and right sides, respectively, of the diagram, where

$$T = \{ \{1, 2\} \}, \quad \theta = \{ \{0\}, \{1, 2\} \}, \quad \theta' = \{ \{0, 1\}, \{2\} \}.$$

Now we can check:

$$\begin{aligned}
 \tilde{\Omega}^{\mathcal{I}}(C(\vec{0})) = \tilde{\Omega}^{\mathcal{I}}(C(0)) &= \nabla^{\mathbf{F}} = \Omega(\text{SEN}^b) \\
 &= \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[0] \leq \Omega(T) \}; \\
 \tilde{\Omega}^{\mathcal{I}}(C(\vec{1})) = \tilde{\Omega}^{\mathcal{I}}(C(1)) &= \theta = \Omega(\text{SEN}^b) \cap \Omega(T) \\
 &= \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[1] \leq \Omega(T) \}; \\
 \tilde{\Omega}^{\mathcal{I}}(C(\vec{2})) = \tilde{\Omega}^{\mathcal{I}}(C(2)) &= \Delta^{\mathbf{F}} = \Omega(\text{SEN}^b) \cap \Omega(T) \cap \Omega(\text{Thm}(\mathcal{I})) \\
 &= \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[2] \leq \Omega(T) \}.
 \end{aligned}$$

We have seen, therefore, through examples, that it is possible, but not necessary, that the left Suszko core of a π -institution satisfies, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, the reverse inclusion of that given in Proposition 864:

$$\tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) \leq \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Intuitively speaking, this means that the left Suszko core $L^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and every Σ -sentence ϕ , the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\vec{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) = \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Based on our preceding work, it is not difficult to see that, if $L^{\mathcal{I}}$ is left soluble, then it is left adequate.

Corollary 867 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $L^{\mathcal{I}}$ is left soluble, then it is left adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned}
 \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) &= \bigcap \{ \Omega(T) : \vec{\phi} \leq T \} \quad (\text{definition of } \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi}))) \\
 &= \bigcap \{ \Omega(T) : \phi \in \overleftarrow{T}_{\Sigma} \} \quad (\text{definition of } \vec{\phi} \text{ and } \overleftarrow{T}) \\
 &= \bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \\
 &\quad (\text{left solubility of } L^{\mathcal{I}} \text{ and Proposition 862})
 \end{aligned}$$

We conclude that $L^{\mathcal{I}}$ is left adequate. ■

Here is an example of a π -institution $\mathcal{I}$, with a left adequate but not left soluble left Suszko core.

Example 868 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the category of natural transformations generated by two unary natural transformations:

- $\rho^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\rho_\Sigma^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given, for all $x \in \mathbf{SEN}^b(\Sigma)$, by

$$\rho_\Sigma^b(x) = \begin{cases} 1, & \text{if } x = 0 \\ 0, & \text{if } x = 1 \\ 2, & \text{if } x = 2 \end{cases}.$$

- $\sigma^b : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$ defined by letting $\sigma_\Sigma^b : \{0, 1, 2\} \rightarrow \{0, 1, 2\}$ be given, for all $x \in \mathbf{SEN}^b(\Sigma)$, by

$$\sigma_\Sigma^b(x) = \begin{cases} 2, & \text{if } x = 0 \\ 1, & \text{if } x = 1 \\ 0, & \text{if } x = 2 \end{cases}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by

$$\mathcal{C}_\Sigma = \{\{2\}, \{0, 2\}, \{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ has four theory families $\text{Thm}(\mathcal{I})$, $T = \{\{0, 2\}\}$, $T' = \{\{1, 2\}\}$ and $\mathbf{SEN}^b$, all of which are theory systems. So it is a systemic π -institution.

The posets of theory families (center), associated Leibniz congruence systems (right) and associated Suszko congruence systems (right, identical with Leibniz congruence systems, since $\mathcal{I}$ is protoalgebraic) are shown in the figure.

Note that $L^{\mathcal{I}} = \{\iota \approx \iota\}$. We show that $L^{\mathcal{I}}$ is left adequate, but not left soluble. We are omitting arrows from the notation in the following verifications since, as $\mathcal{I}$ is based on $\mathbf{F}$ with trivial $\mathbf{Sign}^b$, they play no role in this context.

For left adequacy, we have

$$\begin{aligned}\tilde{\Omega}^{\mathcal{I}}(C(0)) &= \tilde{\Omega}^{\mathcal{I}}(T) = \Delta^{\mathbf{F}} = \bigcap \{\Omega(T'') : T'' \in \text{ThFam}(\mathcal{I})\}; \\ \tilde{\Omega}^{\mathcal{I}}(C(1)) &= \tilde{\Omega}^{\mathcal{I}}(T') = \Delta^{\mathbf{F}} = \bigcap \{\Omega(T'') : T'' \in \text{ThFam}(\mathcal{I})\}; \\ \tilde{\Omega}^{\mathcal{I}}(C(2)) &= \tilde{\Omega}^{\mathcal{I}}(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}} = \bigcap \{\Omega(T'') : T'' \in \text{ThFam}(\mathcal{I})\}.\end{aligned}$$

As for left solubility, note that $L_{\Sigma}^{\mathcal{I}}[0] \leq \Omega(T')$, but that $0 \notin T'_{\Sigma}$. Thus, $L^{\mathcal{I}}$ is not left soluble.

In the opposite direction, and on the positive side, in a left c -reflective π -institution $\mathcal{I}$, if the left Suszko core is left adequate, then it is also left soluble.

First, we note that the following variant of Lemma 827, giving an alternative characterization of left c -reflectivity in terms of both the Suszko and the Leibniz operators, holds.

Lemma 869 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left c -reflective if and only if, for every $T, T' \in \text{ThFam}(\mathcal{I})$,*

$$\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T') \quad \text{implies} \quad \overleftarrow{T} \leq \overleftarrow{T'}.$$

Proof: Assume, first, that $\mathcal{I}$ is left c -reflective and let $T, T' \in \text{ThFam}(\mathcal{I})$, such that $\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$. By the definition of the Suszko operator,

$$\bigcap \{\Omega(T'') : T \leq T'' \in \text{ThFam}(\mathcal{I})\} \leq \Omega(T').$$

Using left c -reflectivity, we get that

$$\bigcap \{\overleftarrow{T''} : T \leq T'' \in \text{ThFam}(\mathcal{I})\} \leq \overleftarrow{T'}.$$

Hence, using Lemma 1, $\overleftarrow{T} \leq \overleftarrow{T'}$, as required.

Suppose, conversely, that, for all $T, T' \in \text{ThFam}(\mathcal{I})$, $\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$ implies $\overleftarrow{T} \leq \overleftarrow{T'}$. Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(\bigcap_{T \in \mathcal{T}} T) &\leq \bigcap_{T \in \mathcal{T}} \tilde{\Omega}^{\mathcal{I}}(T) \quad (\text{monotonicity of } \tilde{\Omega}^{\mathcal{I}}) \\ &\leq \bigcap_{T \in \mathcal{T}} \Omega(T) \quad (\text{since } \tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\ &\leq \Omega(T'). \quad (\text{by hypothesis}) \end{aligned}$$

Using the hypothesis, we conclude that $\overleftarrow{\bigcap_{T \in \mathcal{T}} T} \leq \overleftarrow{T'}$. Thus, by Lemma 3, $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. Therefore, $\mathcal{I}$ is left c-reflective. ■

And now for the promised result showing that in a left c-reflective π -institution $\mathcal{I}$, if the left Suszko core is left adequate, then it is also left soluble.

Proposition 870 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a left c-reflective π -institution based on $\mathbf{F}$. If $L^{\mathcal{I}}$ is left adequate, then it is left soluble.*

Proof: Suppose that $\mathcal{I}$ is left c-reflective and that $L^{\mathcal{I}}$ is left adequate. We must show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$

$$\phi \in \overleftarrow{T}_{\Sigma} \quad \text{iff} \quad L^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 854. For the converse, assume that $L^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T)$. Then, by the left adequacy of $L^{\mathcal{I}}$, we get that $\tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \Omega(T)$. Thus, by left c-reflectivity and Lemma 869, we conclude that $\overleftarrow{C(\overrightarrow{\phi})} \leq \overleftarrow{T}$, which gives $\phi \in \overleftarrow{T}_{\Sigma}$. ■

We finally show that a π -institution is left truth equational if and only if it is left c-reflective and its left Suszko core is left adequate.

$$\begin{aligned} \text{Left Truth Equationality} &= L^{\mathcal{I}} \text{ Left Soluble} \\ &= L^{\mathcal{I}} \text{ Defines Theory Families Up to Arrow} \\ &= \text{Left c-Reflectivity} + L^{\mathcal{I}} \text{ Left Adequate} \end{aligned}$$

Theorem 871 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if it is left c-reflective and has a left adequate left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is left truth equational. Then it is left c-reflective by Theorem 851. Moreover, its left Suszko core is left soluble by Theorem 861 and, hence, by Corollary 867, its left Suszko core is left adequate.

Suppose, conversely, that $\mathcal{I}$ is left c-reflective with a left adequate left Suszko core. Then, by Proposition 870, its left Suszko core is left soluble and, therefore, by Theorem 861, $\mathcal{I}$ is left truth equational. ■

We have now established the following hierarchy of properties:

We give an example of a π -institution which is left truth equational but not (family) truth equational.

Example 872 EXAMPLE NOT FOUND YET!!

11.10 System Truth Equationality

In this section, we look at system truth equationality and system c-reflectivity, which can also be applied to a π -institution without forcing it to be systemic. Recall that, by Proposition ??, system c-reflectivity is a weaker property than left c-reflectivity, i.e., left c-reflectivity, which was used in the characterization of left truth equationality in Section 11.9, implies system c-reflectivity.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 3, Section 3.8, that $\mathcal{I}$ is *system c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

Since left c-reflectivity is not strong enough to imply systemicity, system c-reflectivity has, a fortiori, the same property.

We say that the π -institution $\mathcal{I}$ is **system truth equational** if there exists $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b having a single distinguished argument, such that, for every $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

In that case, we call τ^b a **set of witnessing equations** (of/for the system truth equationality of $\mathcal{I}$).

If $\mathcal{I}$ is a system truth equational π -institution, with witnessing equations τ^b , then, for $T \in \text{ThSys}(\mathcal{I})$, $\tau^b(\Omega(T))$ is exactly equal to T , i.e., the witnessing equations reflect theory systems.

Proposition 873 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is system truth equational, with witnessing equations τ^b , then, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\overleftarrow{\tau}^b(\Omega(T)) = T.$$

Proof: Let $T \in \text{ThSys}(\mathcal{I})$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \overleftarrow{\tau}^b_{\Sigma}(\Omega(T)) & \text{ iff } \tau^b_{\Sigma}[\phi] \leq \Omega(T) \quad (\text{definition}) \\ & \text{ iff } \phi \in T_{\Sigma}. \quad (\text{system truth equationality}) \end{aligned} \quad \blacksquare$$

Proposition 873 has as an immediate consequence the important fact that system truth equationality implies system c-reflectivity.

Theorem 874 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is system truth equational, then it is system c-reflective.*

Proof: Suppose that $\mathcal{I}$ is system truth equational with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} T &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau}^b(\Omega(T)) \quad (\text{Proposition 873}) \\ &= \overleftarrow{\tau}^b(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau}^b(\Omega(T')) \quad (\text{hypothesis and Lemma 94}) \\ &= T'. \quad (\text{Proposition 873}) \end{aligned}$$

Thus, $\mathcal{I}$ is system c-reflective. ■

The following example shows that the implication of Theorem 874 is strict.

Example 875 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:*

- $\mathbf{Sign}^b$ is the trivial category with single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the trivial category of natural transformations.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_{\Sigma} = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and $\mathbf{SEN}^b$, which are also theory systems. Clearly, $\text{Thm}(\mathcal{I}) \leq \mathbf{SEN}^b$. Moreover, $\Omega(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\mathbf{SEN}^b) = \nabla^{\mathbf{F}}$. $\mathcal{I}$ is clearly system c-reflective.

$$\begin{array}{ccc} \mathbf{SEN}^b & \xrightarrow{\quad \quad \quad} & \nabla^{\mathbf{F}} \\ \downarrow & & \downarrow \\ \text{Thm}(\mathcal{I}) & \xrightarrow{\quad \quad \quad} & \Delta^{\mathbf{F}} \end{array}$$

On the other hand, there does not exist $\tau^b \subseteq N^b$, such that I^b has the required properties to constitute a witnessing set of equations for the system truth equationality in $\mathcal{I}$. Any set consisting of projections only cannot satisfy the required condition since $\overleftarrow{\tau^b}(\Omega(T))$ can only be SEN^b or $\overline{\emptyset}$.

We provide, next, a characterization of system truth equationality in terms of the solubility property of the system core of the π -institution. Then, we provide an exact description of those system c-reflective π -institutions which are system truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. First, for $T \in \text{ThSys}(\mathcal{I})$, we define the **systemic Suszko congruence system** of T in $\mathcal{I}$ by

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}(\mathcal{I}) \}.$$

We now define the **system core** of $\mathcal{I}$ to be the collection

$$Z^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \widehat{\Omega}^{\mathcal{I}}(T)) \}.$$

The following proposition clarifies the relation between the Suszko core, the left Suszko core and the system core of a π -institution $\mathcal{I}$.

Proposition 876 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

(a) $S^{\mathcal{I}} \subseteq L^{\mathcal{I}} \subseteq Z^{\mathcal{I}};$

(b) *For every relation family θ on $\mathbf{F}$, $\overleftarrow{Z}^{\mathcal{I}}(\theta) \leq \overleftarrow{L}^{\mathcal{I}}(\theta) \leq \overleftarrow{S}^{\mathcal{I}}(\theta)$.*

Proof: For Part (a), $S^{\mathcal{I}} \subseteq L^{\mathcal{I}}$ has been shown after Proposition 853. For the second inclusion, assume that $\sigma^b \in L^{\mathcal{I}}$ and let $T \in \text{ThSys}(\mathcal{I})$. Then we have

$$\begin{aligned} \sigma^b[T] &= \sigma^b[\overleftarrow{T}] \quad (T \in \text{ThSys}(\mathcal{I})) \\ &\leq \widetilde{\Omega}^{\mathcal{I}}(T) \quad (\sigma^b \in L^{\mathcal{I}}) \\ &\leq \widehat{\Omega}^{\mathcal{I}}(T). \quad (\widetilde{\Omega}^{\mathcal{I}}(T) \leq \widehat{\Omega}^{\mathcal{I}}(T)) \end{aligned}$$

Thus $\sigma^b \in Z^{\mathcal{I}}$ and $L^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$. Part (b) follows from Part (a) and the relevant definitions. ■

The system core of a π -institution satisfies the following property related to the Leibniz congruence systems of the theory systems of the π -institution.

Proposition 877 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $T \in \text{ThSys}(\mathcal{I})$,*

$$T \leq \overleftarrow{Z^{\mathcal{I}}}(\Omega(T)).$$

Proof: Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in T_{\Sigma} & \text{ implies } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) \quad (\text{by definition of } Z^{\mathcal{I}}) \\ & \text{ implies } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad (\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\ & \text{ iff } \phi \in \overleftarrow{Z^{\mathcal{I}}}(\Omega(T)). \quad (\text{by definition}) \end{aligned}$$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is **soluble** if the converse inclusion to that proven in Proposition 877 holds, i.e., if, for all $T \in \text{ThSys}(\mathcal{I})$

$$\overleftarrow{Z^{\mathcal{I}}}(\Omega(T)) \leq T.$$

Equivalently, $Z^{\mathcal{I}}$ is soluble if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \text{ implies } \phi \in T_{\Sigma}.$$

Connecting left solubility of the left Suszko core with solubility of the system core of a π -institution, we now show that the former implies the latter.

Proposition 878 *Let $\mathcal{I} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If the left Suszko core $L^{\mathcal{I}}$ of $\mathcal{I}$ is left soluble, then the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is soluble.*

Proof: Suppose that $L^{\mathcal{I}}$ is left soluble and let $T \in \text{ThSys}(\mathcal{I})$. Then we have

$$\begin{aligned} \overleftarrow{Z^{\mathcal{I}}}(\Omega(T)) & \leq \overleftarrow{L^{\mathcal{I}}}(\Omega(T)) \quad (\text{Proposition 876}) \\ & = T. \quad (\text{hypothesis and Proposition 855}) \end{aligned}$$

Therefore, $Z^{\mathcal{I}}$ is soluble. ■

It turns out that the property of solubility of the system core intrinsically characterizes system truth equationality. We show, first, that the system core being soluble is necessary for system truth equationality. Observe that, in case a π -institution is system truth equational, the witnessing equations form a subset of the system core.

Lemma 879 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is system truth equational, with witnessing equations $\tau^b \subseteq N^b$, then $\tau^b \subseteq Z^{\mathcal{I}}$.*

Proof: By system truth equationality, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T).$$

Thus, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in T_{\Sigma} & \quad \text{iff} \quad (\forall T \leq T' \in \text{ThSys}(\mathcal{I}))(\phi \in T'_{\Sigma}) \\ & \quad \text{iff} \quad (\forall T \leq T' \in \text{ThSys}(\mathcal{I}))(\tau_{\Sigma}^b[\phi] \leq \Omega(T')) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}(\mathcal{I}) \} \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T). \end{aligned}$$

We conclude, by the definition of $Z^{\mathcal{I}}$, that $\tau^b \subseteq Z^{\mathcal{I}}$. ■

Now we prove the necessity of the solubility of the system core for system truth equationality.

Theorem 880 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is system truth equational, then $Z^{\mathcal{I}}$ is soluble.*

Proof: Suppose that $\mathcal{I}$ is system truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) & \quad \text{implies} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{Lemma 879}) \\ & \quad \text{iff} \quad \phi \in T_{\Sigma}. \quad (\text{system truth equationality}) \end{aligned}$$

Thus, $Z^{\mathcal{I}}$ is soluble. ■

The reverse implication completes the promised characterization of system truth equationality in terms of the system core.

Theorem 881 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $Z^{\mathcal{I}}$ is soluble, then $\mathcal{I}$ is system truth equational, with witnessing equations $Z^{\mathcal{I}}$.*

Proof: It suffices to show that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 877, whereas the converse is ensured by the postulated solubility of $Z^{\mathcal{I}}$. ■

Theorems 880 and 881 provide the promised characterization of system truth equationality in terms of the solubility of the system core.

$$\mathcal{I} \text{ is System Truth Equational} \longleftrightarrow Z^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 882 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if $Z^{\mathcal{I}}$ is soluble.*

Proof: Theorem 880 gives the “only if” and the “if” is by Theorem 881. ■

If $\mathcal{I}$ is system truth equational, then the system core defines theory systems in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 873, since $Z^{\mathcal{I}}$ forms a maximal set of witnessing equations of the system truth equationality of $\mathcal{I}$.

Proposition 883 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $Z^{\mathcal{I}}$ is soluble, then, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$T = \overleftarrow{Z^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $Z^{\mathcal{I}}$ is soluble, then, by Theorem 881, $Z^{\mathcal{I}}$ forms a set of witnessing equations for the system truth equationality of $\mathcal{I}$. Therefore, by Proposition 873, we get that, for every $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}}}(\Omega(T))$. ■

This property may be restated as another characterization of system truth equationality. We say that $Z^{\mathcal{I}}$ **defines theory systems** if, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}}}(\Omega(T))$. Then we have:

$\mathcal{I}$ is System Truth Equational $\longleftrightarrow Z^{\mathcal{I}}$ Defines Theory Systems.

Theorem 884 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$T = \overleftarrow{Z^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is system truth equational, then, by Theorem 997, $Z^{\mathcal{I}}$ is soluble. Thus, by Proposition 883, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}}}(\Omega(T))$.

Conversely, if, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}}}(\Omega(T))$, then, $Z^{\mathcal{I}}$ is soluble. Thus, again by Theorem 997, $Z^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is system truth equational. ■

We finally show that the property that separates system complete reflexivity from system truth equationality is a property of the system core that we call adequacy. In analogy with the adequacy of the Suszko core and with the left adequacy of the left Suszko core, this property ensures that the system core is rich enough to define the congruence system $\widehat{\Omega}^{\mathcal{I}}(T)$ of a theory system T in terms of the Leibniz congruence systems of collections of theory systems that it selects via inclusion.

Recall, once more, that given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$, and a sentence family $T \in \text{SenFam}(\mathcal{I})$, we denote by $\overrightarrow{T}$ the least sentence system of $\mathcal{I}$ that includes T (see Proposition 2).

Proposition 885 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \mathbf{ThSys}(\mathcal{I})$,

$$\begin{aligned} \phi \in T_{\Sigma} & \text{ implies } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) \quad (\text{definition of the system core}) \\ & \text{ implies } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T). \quad (\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{aligned}$$

Therefore, we have

$$\begin{aligned} & \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ & \leq \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } \phi \in T_{\Sigma} \} \\ & = \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } \vec{\phi} \leq T \} \\ & = \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})). \end{aligned}$$

Therefore, the displayed inclusion always holds. ■

It is possible, but not necessary, that the system core of a π -institution satisfies, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, the reverse inclusion of that given in Proposition 885:

$$\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) \leq \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Intuitively speaking, this means that the system core $Z^{\mathcal{I}}$ is rich enough to allow, for every Σ -sentence ϕ , the determination of those theory systems whose Leibniz congruence systems form a covering of the congruence system $\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi}))$ associated with $C(\vec{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the system core $Z^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) = \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Based on our preceding work, it is not difficult to see that, if $Z^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 886 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $Z^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) &= \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } \vec{\phi} \leq T \} \\ & \quad (\text{definition of } \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi}))) \\ &= \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } \phi \in T \} \\ & \quad (T \in \mathbf{ThSys}(\mathcal{I})) \\ &= \bigcap \{ \Omega(T) : T \in \mathbf{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \\ & \quad (\text{solubility of } Z^{\mathcal{I}} \text{ and Proposition 883}) \end{aligned}$$

We conclude that $Z^{\mathcal{I}}$ is adequate. ■

As a partial converse, in a *system c-reflective* π -institution $\mathcal{I}$, if the system core is adequate, then it is also soluble.

First, we prove the following variant of Lemma 827, giving an alternative characterization of system c-reflectivity in terms of both $\widehat{\Omega}^{\mathcal{I}}$ and the Leibniz operator.

Lemma 887 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system c-reflective if and only if, for every $T, T' \in \text{ThSys}(\mathcal{I})$,*

$$\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T') \quad \text{implies} \quad T \leq T'.$$

Proof: Assume, first, that $\mathcal{I}$ is system c-reflective and let $T, T' \in \text{ThSys}(\mathcal{I})$, such that $\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$. By the definition of the hat operator,

$$\bigcap \{ \Omega(T'') : T \leq T'' \in \text{ThSys}(\mathcal{I}) \} \leq \Omega(T').$$

Using system c-reflectivity, we get that

$$\bigcap \{ T'' : T \leq T'' \in \text{ThSys}(\mathcal{I}) \} \leq T'.$$

Hence, we conclude $T \leq T'$, as required.

Suppose, conversely, that, for all $T, T' \in \text{ThSys}(\mathcal{I})$, $\widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T')$ implies $T \leq T'$. Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \widehat{\Omega}^{\mathcal{I}}(\bigcap_{T \in \mathcal{T}} T) &\leq \bigcap_{T \in \mathcal{T}} \widehat{\Omega}^{\mathcal{I}}(T) \quad (\text{monotonicity of } \widehat{\Omega}^{\mathcal{I}}) \\ &\leq \bigcap_{T \in \mathcal{T}} \Omega(T) \quad (\text{since } \widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \\ &\leq \Omega(T'). \quad (\text{by hypothesis}) \end{aligned}$$

Using the hypothesis, we conclude that $\bigcap_{T \in \mathcal{T}} T \leq T'$. Therefore, $\mathcal{I}$ is system c-reflective. ■

And now for the promised result showing that in a system c-reflective π -institution $\mathcal{I}$, if the system core is adequate, then it is also soluble.

Proposition 888 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a system c-reflective π -institution based on $\mathbf{F}$. If the system core $Z^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is system c-reflective and that $Z^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 877. For the converse, assume that $Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by the adequacy of $Z^{\mathcal{I}}$, we get

that $\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) \leq \Omega(T)$. Thus, by system c-reflectivity and Lemma 887, we conclude that $C(\vec{\phi}) \leq T$, which gives $\phi \in T_{\Sigma}$. ■

We finally show that a π -institution is system truth equational if and only if it is system c-reflective and its system core is adequate.

$$\begin{aligned} \text{System Truth Equationality} &= Z^{\mathcal{I}} \text{ Left Soluble} \\ &= Z^{\mathcal{I}} \text{ Defines Theory Systems} \\ &= \text{System c-Reflectivity} + Z^{\mathcal{I}} \text{ Adequate} \end{aligned}$$

Theorem 889 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if it is system c-reflective and has an adequate system core.*

Proof: Suppose, first, that $\mathcal{I}$ is system truth equational. Then it is system c-reflective by Theorem 874. Moreover, its system core is soluble by Theorem 997 and, hence, by Corollary 886, its system core is adequate.

Suppose, conversely, that $\mathcal{I}$ is system c-reflective with an adequate system core. Then, by Proposition 888, its system core is soluble and, therefore, by Theorem 997, $\mathcal{I}$ is system truth equational. ■

We have now established the following hierarchy of properties:

We give an example of a π -institution which is system truth equational but not left truth equational.

Example 890 **EXAMPLE NOT FOUND YET!!**

Chapter 12

The Syntactic Leibniz Hierarchy: Edifice

12.1 Introduction

In this chapter, we develop the syntactic machinery of translations, interpretations and equivalences in order to characterize syntactic analogs of the various types of prealgebraizable and algebraizable π -institutions studied in Chapter 4. The roots of these investigations can be traced back to the famous “Memoir monograph” of Blok and Pigozzi [36]. Of course various advancements, refinements and generalizations have been presented in the literature since then, e.g., in [41, 53, 50, 74, 82] and in the categorical setting [106]. The monograph [65] and the textbook [89] give a more comprehensive list of more recent approaches pertaining to the sentential logic case.

Section 12.2 introduces π -structures, a variant of π -institutions that may lack structurality. By analogy with the terminology concerning theory families and theory systems, their closures are termed *closure families* rather than closure systems. Introduced, also, are *transformations* between algebraic systems and *interpretations* between π -structures. Let us consider, for concreteness, two algebraic systems $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$. A *translation* $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$ from $\mathbf{K}$ to $\mathbf{K}'$ is a collection $\alpha = \{\alpha_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ of mappings

$$\alpha_\Sigma : \text{SEN}(\Sigma) \rightarrow \text{SenFam}(\mathbf{K}')$$

from Σ -sentences of $\mathbf{K}$ to sentence families of $\mathbf{K}'$. Now, given two π -structures $\mathcal{K} = \langle \mathbf{K}, D \rangle$ based on $\mathbf{K}$ and $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ based on $\mathbf{K}'$, a translation $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$ is an *interpretation* $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ from $\mathcal{K}$ to $\mathcal{K}'$ if, for every signature Σ of $\mathcal{K}$ and all Σ -sentences $\Phi \cup \{\phi\}$,

$$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma[\phi] \leq D'(\alpha_\Sigma[\Phi]).$$

If such an α exists, then $\mathcal{K}$ is said to be *interpretable* in $\mathcal{K}'$. Two interpretations $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ and $\beta : \mathcal{K}' \rightarrow \mathcal{K}$, acting in opposite directions, are called *inverses* and $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ a *conjugate pair* if, for all $\Sigma \in |\mathbf{Sign}|$, all $\Sigma' \in |\mathbf{Sign}'|$ and all $\phi \in \text{SEN}(\Sigma)$, $\psi \in \text{SEN}'(\Sigma')$,

$$D(\phi) = D(\beta[\alpha_\Sigma[\phi]]) \quad \text{and} \quad D'(\psi) = D'(\alpha[\beta_{\Sigma'}[\psi]]).$$

Two π -structures are called *equivalent* if there exist inverse interpretations in both directions. As in the classical case of sentential logics, not all four conditions required for equivalence are independent. The first of the interpretation conditions and the second invertibility condition imply the other two and vice versa. This was originally pointed out by Blok and Pigozzi in Corollary 2.9 of [36] in the context of interpretations between a sentential logic and an equational logic over the same algebraic signature.

Given a translation $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$, one may define a mapping

$$\alpha^* : \text{SenFam}(\mathbf{K}') \rightarrow \text{SenFam}(\mathbf{K}),$$

called the *residual* of α . Such a mapping, when applied to interpretations $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ between π -structures $\mathcal{K}$ and $\mathcal{K}'$, yields a mapping $\alpha^* : \text{ThFam}(\mathcal{K}') \rightarrow \text{ThFam}(\mathcal{K})$. Additionally, if $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$, then $\text{ThFam}(\mathcal{K}') \overset{\alpha^*}{\underset{\beta^*}{\rightleftarrows}} \text{ThFam}(\mathcal{K})$ is a pair of inverse mappings. These establish an order isomorphism between the complete lattice of theory families of $\mathcal{K}'$ and the complete lattice of theory families of $\mathcal{K}$. The process by which a conjugate pair of interpretations α and β gives rise to the order isomorphisms α^* and β^* can be reversed. This direction occupies the second part of Section 12.2.

Suppose $h : \text{ThFam}(\mathcal{K}') \rightarrow \text{ThFam}(\mathcal{K})$ is an order isomorphism. We define translations $\vec{h} = \{\vec{h}_\Sigma\}_{\Sigma \in |\mathbf{Sign}|} : \mathbf{K} \rightarrow \mathbf{K}'$ and $\overleftarrow{h} = \{\overleftarrow{h}_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}'|} : \mathbf{K}' \rightarrow \mathbf{K}$ by setting, for all $\Sigma \in |\mathbf{Sign}|$, all $\phi \in \text{SEN}(\Sigma)$, all $\Sigma' \in |\mathbf{Sign}'|$ and all $\psi \in \text{SEN}'(\Sigma')$,

$$\vec{h}_\Sigma(\phi) = h^{-1}(D(\phi)) \quad \text{and} \quad \overleftarrow{h}_{\Sigma'}(\psi) = h(D'(\psi)).$$

It is shown that $\vec{h} : \mathcal{K} \rightarrow \mathcal{K}'$ and $\overleftarrow{h} : \mathcal{K}' \rightarrow \mathcal{K}$ are interpretations and, moreover, that $(\vec{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ forms a conjugate pair. Finally, it is shown that the residuals $\vec{h}^*$ and $\overleftarrow{h}^*$ coincide with h and h^{-1} , respectively.

In Section 12.3, we single out a special type of translation, which is closely connected to the syntactic apparatus of a given algebraic system, in particular of one that is the base algebraic system on which a π -institution is built. More precisely, instead of considering arbitrary maps from a sentence functor into the sentence families over another sentence functor, we specialize to the case in which the mappings occur between different powers of the same sentence functor, akin to the framework of k -deductive systems of Blok and Pigozzi [41]. In this special case, arbitrary translations may be replaced by *transformations*, i.e., sets of natural transformations, possibly with parameters. Those are said to be *natural*, i.e., are called *natural transformations*, if they are parameter free. Inherited by the special case of transformations from the general case of translations from Section 12.2 are the notions of interpretability and of equivalence between π -structures. Virtually all results involving arbitrary translations and interpretations are specialized here to the case of transformations and natural transformations and of interpretations induced by transformations. Accompanying those is the notion of a *transformational order isomorphism* between lattices of theory families which reflects the fact that those isomorphisms are induced by transformations rather than by arbitrary translations. It is shown that, if there exists a transformational order isomorphism between lattices of theory families, then the pair of transformations that induce the isomorphism do form a conjugate pair between the corresponding π -structures and, consequently, these two π -structures are equivalent. Similar results apply if arbitrary transformations are replaced by natural transformations.

In the sentential logic framework, the passage from arbitrary interpretations to ones between k -deductive systems serves in transitioning from general equivalences to equivalences between a deductive system and an equational deductive system, which defines algebraizability (albeit the development of this passage occurred in reverse chronological order). Similarly, here, the passage from arbitrary translations and interpretations to transformations and interpretations based on transformations serves an analogous purpose.

The second part of Section 12.3 introduces *equational π -structures*. Those, roughly speaking, are the ones in which reflexivity, symmetry, transitivity, compatibility (or congruence) and invariance under signature morphisms hold. In a characterization theorem governing these structures, it is shown that a π -structure is equational if and only if its closure systems are congruence systems on the underlying algebraic system of the π -structure if and only if it is one induced on the underlying algebraic system $\mathbf{F}$ by a certain class of $\mathbf{F}$ -algebraic systems. The notion of an equational π -structure facilitates connecting the framework of equivalence between π -structures with that of syntactic protoalgebraicity and of (family) truth equationality, studied in Sections 11.3 and 11.6, respectively, of Chapter 11. Namely, it is shown that, if a π -institution is equivalent to an equational π -structure over the same underlying algebraic system via a conjugate pair of transformations, then it is syntactically protoalgebraic and truth equational with witnessing transformations and equations those constituting the conjugate pair. Finally, in an analog of a well known result of Blk and Pigozzi (Theorem 2.15 of [36]), it is shown that equivalence of a π -institution with an equational π -structure via transformations can only occur in an essentially unique way in the sense that any two such π -structures must be identical and, furthermore, the transformations serving the purpose must be unique up to deductive closure.

In Chapter 4, we defined the class of weakly family algebraizable (WF algebraizable) π -institutions. Weak family algebraizability is characterized by protoalgebraicity (family monotonicity) and family injectivity of the Leibniz operator. In Section 12.4, the goal is to define a syntactic counterpart of this class. Critical here are the results obtained in Chapter 11 which connect syntactic protoalgebraicity and protoalgebraicity via the Leibniz property of the reflexive core $R^{\mathcal{I}}$ and, also, truth equationality and family c-reflectivity via the adequacy property of the Suszko core $S^{\mathcal{I}}$. Starting from these, we say that a π -institution $\mathcal{I}$ is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified if it has a Leibniz reflexive core and an adequate Suszko core and, further, declare that a π -institution is *syntactically weakly family algebraizable* (*syntactically WF algebraizable*) if it is protoalgebraic, family injective and $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified. This definition seems to be the “right” one for a syntactic counterpart of weakly family algebraizable π -institutions. According to this, e.g., syntactically WF algebraizable π -institutions are characterized as those which are, at the same time, syntactically protoalgebraic and family truth equational. Moreover, they are exactly those that are WF algebraizable and $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified. Another char-

acterization obtained from this and one for WF algebraizability asserts that $\mathcal{I}$ is syntactically WF algebraizable if and only if it is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. Yet another characterization uses the notion of equivalence with an equational π -structure introduced in Section 12.3. Recall from Chapter 2, Section 2.7, that $\text{AlgSys}^*(\mathcal{I})$ is the class of all $\mathbf{F}$ -algebraic systems that are algebraic system reducts of reduced $\mathcal{I}$ -matrix families. We define the collection $\text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ of congruence systems on $\mathcal{A}$ whose quotients are algebraic systems in $\text{AlgSys}^*(\mathcal{I})$. An alternative characterization of $\text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is that it consists of all those congruence systems on $\mathcal{A}$ that are Leibniz congruence systems of some $\mathcal{I}$ -filter family of $\mathcal{A}$. In general, the collection of all $\mathcal{I}^*$ -congruence systems on an $\mathbf{F}$ -algebraic system $\mathcal{A}$ is not closed under signature-wise intersections and, therefore, does not form a closure family on $\mathcal{A}^2$. However, this turns out to be the case if the π -institution happens to be protoalgebraic. Specializing to the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, we get that, provided $\mathcal{I}$ is protoalgebraic, $\text{ConSys}^{\mathcal{I}*}(\mathcal{F})$ is closed under arbitrary intersections. This enables us to define an equational π -structure $\mathcal{Q}^{\mathcal{I}*} = \langle \mathbf{F}^2, D^{\mathcal{I}*} \rangle$, where $D^{\mathcal{I}*}$ is the closure operator associated with the closure family $\text{ConSys}^{\mathcal{I}*}(\mathcal{F})$. The first indication that this definition serves well our purposes is the result asserting that, if a π -institution is syntactically WF algebraizable, then, with $I^b : (\text{SEN}^b)^{\omega} \rightarrow \text{SEN}^b$, with two distinguished arguments, being the collection of witnessing transformations of the syntactic protoalgebraicity of $\mathcal{I}$ and with $\tau^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ with a single distinguished argument, being the collection of witnessing equations of the truth equationality of $\mathcal{I}$, $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via the conjugate pair $(\tau^b, \vec{I}^b) : \mathcal{I} \rightleftharpoons \mathcal{Q}^{\mathcal{I}*}$. Putting many preceding results together, we obtain a fundamental characterization of syntactic WF algebraizability, tracing its origins to the seminal “Memoirs monograph” [36] of Blok and Pigozzi. Namely, a π -institution $\mathcal{I}$ is syntactically WF algebraizable if and only if it is equivalent to its associated equational π -structure $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftharpoons \mathcal{Q}^{\mathcal{I}*}$ of transformations. More generally, $\mathcal{I}$ is syntactically WF algebraizable if and only if it is equivalent to an equational π -structure via a conjugate pair of transformations. Finally, this generalized version implies that $\mathcal{I}$ is syntactically WF algebraizable if and only if there exists a transformational isomorphism between its lattice of theory families and the lattice of theory families of an equational π -structure.

Syntactic weak family algebraizability encompasses family reflectivity, which implies systemicity. Thus, if a π -institution is syntactically WF algebraizable, it must necessarily be systemic. This leads to the idea of considering weaker types of syntactic algebraizability admitting also non-systemic π -institutions. This endeavor is pursued in Sections 12.5 and 12.6. Section 12.5 considers *syntactic weak algebraizability*. The development parallels that of Section 12.4.

We say that a π -institution is $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified if it has a Leibniz reflexive core $R^{\mathcal{I}}$ and a left adequate left Suszko core $L^{\mathcal{I}}$. $\mathcal{I}$ is *syntactically weakly algebraizable* (*syntactically W algebraizable*) if it is protoalgebraic, system injective and $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified. Syntactic weak algebraizability is characterized as the conjunction of syntactic protoalgebraicity and either system or left truth equationality. Moreover, $\mathcal{I}$ is syntactically W algebraizable if and only if it is weakly algebraizable and $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified. Yet another characterization using isomorphisms asserts that $\mathcal{I}$ is syntactically W algebraizable if and only if it is $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism.

In the second part of Section 12.5, we give a characterization of syntactic W algebraizability using the equational counterpart $\mathcal{Q}^{\mathcal{I}*}$ of a π -institution $\mathcal{I}$. This mimics in style the fundamental characterization of syntactic weak family algebraizability, presented in Section 12.4. First, given a π -institution $\mathcal{I}$, we define a π -structure $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$, called the *systemic skeleton* of $\mathcal{I}$, by taking $K^{\mathcal{I}}$ to be the closure operator whose theory families are the theory systems of $\mathcal{I}$. This π -structure is not a π -institution in general, since $K^{\mathcal{I}}$ may fail to be structural. We show, nevertheless, that, if a π -institution $\mathcal{I}$ is syntactically W algebraizable, then its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to its equational counterpart $\mathcal{Q}^{\mathcal{I}*}$ via the conjugate pair $(\tau^b, \vec{I}^b)$ of transformations, where I^b witnesses syntactic protoalgebraicity and τ^b witnesses left truth equationality. Conversely, if $\mathcal{I}$ is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to the equational counterpart $\mathcal{Q}^{\mathcal{I}*}$ of $\mathcal{I}$ via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically weakly algebraizable. More generally, we show that syntactic weak algebraizability is characterized by stability plus the existence of an equivalence between its systemic skeleton and an equational π -structure via a conjugate pair of transformations. This characterization yields also that $\mathcal{I}$ is syntactically W algebraizable if and only if it is stable and there exists a transformational order isomorphism between the lattice of its theory systems and that of the theory families of an equational π -institution.

Syntactic weak algebraizability is broad enough to accommodate non-systemic π -institutions, but it is still too narrow to allow non-stable π -institutions to be considered. So in Section 12.6, we further weaken the required conditions so as to be able to also include non-stable π -institutions. We say that a π -institution $\mathcal{I}$ is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified if its reflexive core $R^{\mathcal{I}}$ is Leibniz and its system core $Z^{\mathcal{I}}$ is adequate. Then $\mathcal{I}$ is called *syntactically weakly system prealgebraizable* (*syntactically WS prealgebraizable*) if it is prealgebraic, system injective and $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified. According to this definition, $\mathcal{I}$ is syntactically WS prealgebraizable if and only if it is syntactically prealgebraic and system truth equational. Moreover, $\mathcal{I}$ is syntactically WS prealgebraizable if and only if it is weakly system prealgebraizable and $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified. In terms of isomorphisms between theory and congruence lattices, we get that

$\mathcal{I}$ is syntactically WS prealgebraizable if and only if it is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order embedding.

To characterize syntactic WS prealgebraizability via an equivalence between π -structures, we use again the systemic skeleton $\mathcal{K}^{\mathcal{I}}$ of $\mathcal{I}$, but we need to introduce an equational π -structure induced by $\mathcal{I}$ different from the equational π -structure $\mathcal{Q}^{\mathcal{I}*}$ associated with $\mathcal{I}$. To this end, instead of the collection $\text{AlgSys}^*(\mathcal{I})$ of all algebraic system reducts of reduced $\mathcal{I}$ -filter families, we use the collection $\text{AlgSys}^{\bullet}(\mathcal{I})$ of all algebraic system reducts of reduced $\mathcal{I}$ -filter systems. Then we define the class of $\mathcal{I}^{\bullet}$ -congruence systems $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ on an $\mathbf{F}$ -algebraic system $\mathcal{A}$ as the collection of all those congruence systems θ on $\mathcal{A}$, such that $\mathcal{A}/\theta \in \text{AlgSys}^{\bullet}(\mathcal{I})$. Alternatively, $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ may be characterized as the collection of all congruence systems on $\mathcal{A}$ which are images under $\Omega^{\mathcal{A}}$ of $\mathcal{I}$ -filter systems on $\mathcal{A}$. Assuming prealgebraicity of a π -institution $\mathcal{I}$, we can show that $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ is closed under arbitrary signature-wise intersections. In particular, this holds for the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, whence one may consider the *systemic equational π -structure* $\mathcal{Q}^{\mathcal{I}\bullet} = \langle \mathbf{F}^2, D^{\mathcal{I}\bullet} \rangle$ associated with $\mathcal{I}$, where $D^{\mathcal{I}\bullet}$ is the closure operator corresponding to the closure family $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{F})$. With this machinery at hand, it is shown that, if $\mathcal{I}$ is syntactically WS prealgebraizable, then $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via the conjugate pair $(\tau^{\flat}, I^{\flat})$ of transformations, where $I^{\flat}$ witnesses the syntactic prealgebraicity of $\mathcal{I}$ and $\tau^{\flat}$ witnesses the system truth equationality of $\mathcal{I}$. Conversely, if the systemic skeleton $\mathcal{K}^{\mathcal{I}}$ of $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically WS prealgebraizable. More generally, $\mathcal{I}$ is syntactically WS prealgebraizable if and only if its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of transformations. This characterization enables us to show that syntactic WS prealgebraizability is also characterized by the existence of a transformational order isomorphism between the lattice of theory systems of $\mathcal{I}$ and that of the theory families of an equational π -structure.

In Section 12.5, we studied syntactically weakly algebraizable π -institutions, one of the motivations being opening syntactic weak algebraizability to non-systemic π -institutions. Subsequently, in Section 12.6, we studied syntactically weakly system prealgebraizable π -institutions, weaker than syntactically weakly algebraizable ones, able to also encompass some non-stable π -institutions. Section 12.7 aims to bridge a gap between syntactic WS prealgebraizability and syntactic W algebraizability, which becomes apparent when one compares with the corresponding semantic hierarchy of Chapter 4. Recall that a π -institution $\mathcal{I}$ is $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified if its reflexive core $R^{\mathcal{I}}$ is Leibniz and its left Suszko core $L^{\mathcal{I}}$ is left adequate. We call $\mathcal{I}$ *syntactically weakly left c-reflectively prealgebraizable* (syntactically WLC prealgebraizable) if it is prealgebraic, left c-reflective and $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified. Based on previously

obtained characterizations of syntactic prealgebraicity and of left truth equationality, we get that syntactic WLC prealgebraizability is the conjunction of syntactic prealgebraicity and of left truth equationality. Moreover, $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is WLC prealgebraizable and $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified. In terms of morphisms between lattices of theory systems and of congruence systems, $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left completely order reflecting surjection, restricting to an order embedding $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Further, in terms of equivalences, syntactic WLC prealgebraizability is characterized by left truth equationality plus an equivalence of the systemic skeleton of the π -institution with an equational π -structure via a conjugate pair of transformations. In terms of isomorphisms between lattices of theory families, we have that a π -institution $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is left truth equational and there exists a transformational order isomorphism between the lattice of its theory systems and that of an equational π -structure. In concluding the section and the chapter, a complete subhierarchy of the various (semantic) prealgebraizability and syntactic prealgebraizability classes is presented. This is reproduced here in lieu of a summary and to provide an overview of the location of the syntactic classes in the overall hierarchy.

12.2 Translations

In this section we discuss translations, interpretations and equivalence that will be used later in the context of algebraizable π -institutions. In the context of algebraizability, the algebraic counterparts of π -institutions may consist of algebraic closure families that lack the property of structurality, i.e., they are not closure systems, as introduced previously. Since these closure families are not structural in general, the corresponding algebraic structures do not constitute π -institutions. To accommodate these, we deal with more general structures that include all π -institutions, but also pairs of algebraic systems and closure families that are non-structural. We call these π -structures.

Definition 891 *A π -structure $\mathcal{K} = \langle \mathbf{K}, D \rangle$ is a pair consisting of:*

- *an algebraic system $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$;*
- *a $|\mathbf{Sign}|$ -indexed family $D = \{D_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ of closure operators $D_\Sigma : \mathcal{P}\text{SEN}(\Sigma) \rightarrow \mathcal{P}\text{SEN}(\Sigma)$, $\Sigma \in |\mathbf{Sign}|$.*

*Such a family D is called a **closure family** on $\mathbf{K}$.*

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be two algebraic systems. A **translation** $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$ is a collection

$$\alpha = \{\alpha_\Sigma\}_{\Sigma \in |\mathbf{Sign}|},$$

where, for all $\Sigma \in |\mathbf{Sign}|$,

$$\alpha_\Sigma : \text{SEN}(\Sigma) \rightarrow \text{SenFam}(\mathbf{K}')$$

assigns to each Σ -sentence ϕ of $\mathbf{K}$ a sentence family

$$\alpha_\Sigma[\phi] = \{\alpha_{\Sigma, \Sigma'}[\phi]\}_{\Sigma' \in |\mathbf{Sign}'|}.$$

For $\Sigma \in |\mathbf{Sign}|$, $\Phi \subseteq \text{SEN}(\Sigma)$, we set

$$\alpha_\Sigma[\Phi] = \bigcup \{\alpha_\Sigma[\phi] : \phi \in \Phi\},$$

where the union is, as usual, taken signature-wise and, hence, $\alpha_\Sigma[\Phi] \in \text{SenFam}(\mathbf{K}')$. More generally, for $T \in \text{SenFam}(\mathbf{K})$, we set

$$\alpha[T] = \bigcup \{\alpha_\Sigma[T_\Sigma] : \Sigma \in |\mathbf{Sign}|\}.$$

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems and $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}, \mathbf{K}'$, respectively. An

interpretation $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ is a translation $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma[\phi] \leq D'(\alpha_\Sigma[\Phi]).$$

If such an interpretation exists, then $\mathcal{K}$ is said to be **interpretable in $\mathcal{K}'$** .

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems and $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively. Let, also,

$$\alpha : \mathcal{K} \rightarrow \mathcal{K}' \quad \text{and} \quad \beta : \mathcal{K}' \rightarrow \mathcal{K}$$

be interpretations from $\mathcal{K}$ to $\mathcal{K}'$ and from $\mathcal{K}'$ to $\mathcal{K}$, respectively. α and β are said to be **inverses** of each other and the pair $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is referred to as a **conjugate pair** if:

- for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$D(\phi) = D(\beta[\alpha_\Sigma[\phi]]);$$

- for all $\Sigma' \in |\mathbf{Sign}'|$ and all $\psi \in \text{SEN}'(\Sigma')$,

$$D'(\psi) = D'(\alpha[\beta_{\Sigma'}[\psi]]).$$

The π -structures $\mathcal{K}$ and $\mathcal{K}'$ are called **equivalent** if there exists a conjugate pair $\mathcal{K} \xrightarrow{(\alpha, \beta)} \mathcal{K}'$.

Lemma 892 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$, $\beta : \mathbf{K}' \rightarrow \mathbf{K}$ translations. The following are equivalent:*

- (i) $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ is an interpretation and, for all $\Sigma' \in |\mathbf{Sign}'|$, $\psi \in \text{SEN}'(\Sigma')$, $D'(\psi) = D'(\alpha[\beta_{\Sigma'}[\psi]]);$
- (ii) $\beta : \mathcal{K}' \rightarrow \mathcal{K}$ is an interpretation and, for all $\Sigma \in |\mathbf{Sign}|$, $\phi \in \text{SEN}(\Sigma)$, $D(\phi) = D(\beta[\alpha_\Sigma[\phi]]).$

Proof: By symmetry, it suffices to show (i) $\Rightarrow$ (ii).

Suppose, first, that $\Sigma' \in |\mathbf{Sign}'|$ and $\Psi \cup \{\psi\} \subseteq \text{SEN}'(\Sigma')$. Then, we have

$$\begin{aligned} \psi \in D'_{\Sigma'}(\Psi) & \quad \text{iff} \quad D'(\psi) \leq D'(\Psi) \quad (\text{Property of } D') \\ & \quad \text{iff} \quad D'(\alpha[\beta_{\Sigma'}[\psi]]) \leq D'(\alpha[\beta_{\Sigma'}[\Psi]]) \quad (\text{Hypothesis}) \\ & \quad \text{iff} \quad \alpha[\beta_{\Sigma'}[\psi]] \leq D'(\alpha[\beta_{\Sigma'}[\Psi]]) \quad (\text{Property of } D') \\ & \quad \text{iff} \quad \beta_{\Sigma'}[\psi] \leq D(\beta_{\Sigma'}[\Psi]). \quad (\text{Hypothesis}) \end{aligned}$$

So $\beta : \mathcal{K}' \rightarrow \mathcal{K}$ is an interpretation.

Assume, next, that $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$. Then, by the hypothesis applied to $\alpha_\Sigma[\phi] \in \text{SenFam}(\mathbf{K}')$, we have

$$D'(\alpha[\beta[\alpha_\Sigma[\phi]]]) = D'(\alpha_\Sigma[\phi]).$$

Hence, we get that

$$\alpha_\Sigma[\phi] \leq D'(\alpha[\beta[\alpha_\Sigma[\phi]]]) \quad \text{and} \quad \alpha[\beta[\alpha_\Sigma[\phi]]] \leq D'(\alpha_\Sigma[\phi]).$$

Therefore, by the fact that α is an interpretation,

$$\phi \in D_\Sigma(\beta[\alpha_\Sigma[\phi]]) \quad \text{and} \quad \beta[\alpha_\Sigma[\phi]] \leq D(\phi).$$

So we conclude that $D(\phi) = D(\beta[\alpha_\Sigma[\phi]])$. ■

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems and $\alpha : \mathbf{K} \rightarrow \mathbf{K}'$ a translation. Define the **residual α^* of the translation α** ,

$$\alpha^* : \text{SenFam}(\mathbf{K}') \rightarrow \text{SenFam}(\mathbf{K})$$

by letting, for all $T' \in \text{SenFam}(\mathbf{K}')$,

$$\alpha^*(T') = \{\alpha_\Sigma^*(T')\}_{\Sigma \in |\mathbf{Sign}|}$$

be given, for all $\Sigma \in |\mathbf{Sign}|$, by

$$\alpha_\Sigma^*(T') = \{\phi \in \text{SEN}(\Sigma) : \alpha_\Sigma[\phi] \leq T'\}.$$

The following proposition shows that, when applied to interpretations between π -structures the star operator restricts to mappings from theory families to theory families.

Proposition 893 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ an interpretation. Then, for all $T' \in \text{ThFam}(\mathcal{K}')$, $\alpha^*(T') \in \text{ThFam}(\mathcal{K})$.*

Proof: Suppose $T' \in \text{ThFam}(\mathcal{K}')$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\alpha_\Sigma^*(T'))$. Then, since $\alpha : \mathcal{K} \rightarrow \mathcal{K}'$ is an interpretation, we have

$$\alpha_\Sigma[\phi] \leq D'(\alpha[\alpha_\Sigma^*(T')]) \leq D'(T') = T'.$$

Hence $\phi \in \alpha_\Sigma^*(T')$. Since $\Sigma \in |\mathbf{Sign}|$ was arbitrary, we conclude that $\alpha_\Sigma^*(T') \in \text{ThFam}(\mathcal{K})$. ■

In addition, we show that, when $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ form a conjugate pair, then $\beta^* : \text{ThFam}(\mathcal{K}) \rightarrow \text{ThFam}(\mathcal{K}')$ and $\alpha^* : \text{ThFam}(\mathcal{K}') \rightarrow \text{ThFam}(\mathcal{K})$ are inverse mappings.

Lemma 894 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ a conjugate pair. Then, for all $T \in \text{ThFam}(\mathcal{K})$,*

$$\alpha^*(\beta^*(T)) = T.$$

Proof: Suppose $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair, $T \in \text{ThFam}(\mathcal{K})$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$. Then we have

$$\begin{aligned} \phi \in \alpha_\Sigma^*(\beta^*(T)) & \text{ iff } \alpha_\Sigma[\phi] \leq \beta^*(T) \quad (\text{Definition of } \alpha^*) \\ & \text{ iff } \beta[\alpha_\Sigma[\phi]] \leq T \quad (\text{Definition of } \beta^*) \\ & \text{ iff } D(\beta[\alpha_\Sigma[\phi]]) \leq T \quad (T \in \text{ThFam}(\mathcal{K})) \\ & \text{ iff } D_\Sigma(\phi) \leq T_\Sigma \quad ((\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}') \\ & \text{ iff } \phi \in T_\Sigma. \quad (T \in \text{ThFam}(\mathcal{K})) \end{aligned}$$

Thus, we conclude that $\alpha^*(\beta^*(T)) = T$. ■

Based on Lemma 894, we can show that $\beta^* : \text{ThFam}(\mathcal{K}) \rightarrow \text{ThFam}(\mathcal{K}')$ and $\alpha^* : \text{ThFam}(\mathcal{K}') \rightarrow \text{ThFam}(\mathcal{K})$ are bijections.

Lemma 895 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ a conjugate pair. Then $\alpha^* : \text{ThFam}(\mathcal{K}') \rightarrow \text{ThFam}(\mathcal{K})$ is a bijection.*

Proof: Let $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ be a conjugate pair. First, by Proposition 893, $\alpha^* : \text{ThFam}(\mathcal{K}') \rightarrow \text{ThFam}(\mathcal{K})$ is well-defined. To see that it is surjective, let $T \in \text{ThFam}(\mathcal{K})$. Then, by Proposition 893, $\beta^*(T) \in \text{ThFam}(\mathcal{K}')$ and, by Lemma 894, $\alpha^*(\beta^*(T)) = T$. Thus, α^* is indeed surjective. For injectivity, assume $S', T' \in \text{ThFam}(\mathcal{K}')$, such that $\alpha^*(S') = \alpha^*(T')$. Then, by surjectivity, there exist $S, T \in \text{ThFam}(\mathcal{K})$, such that $\beta^*(S) = S'$ and $\beta^*(T) = T'$. Therefore, we get

$$S = \alpha^*(\beta^*(S)) = \alpha^*(S') = \alpha^*(T') = \alpha^*(\beta^*(T)) = T.$$

But then we get $S' = \beta^*(S) = \beta^*(T) = T'$. we conclude that α^* is also injective and, hence, it is a bijection. ■

In the main theorem of this section, it is shown that if $\mathcal{K}$ and $\mathcal{K}'$ are equivalent π -structures via a conjugate pair $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$, then $\beta^* : \mathbf{ThFam}(\mathcal{K}) \rightarrow \mathbf{ThFam}(\mathcal{K}')$ and $\alpha^* : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ form a pair of mutually inverse order isomorphisms between the complete lattices of the corresponding theory families.

Recall that, given a π -institution $\mathcal{I}$, we denote by

$$\mathbf{ThFam}(\mathcal{I}) = \langle \text{ThFam}(\mathcal{I}), \leq \rangle$$

the complete lattice of theory families of $\mathcal{I}$ ordered by signature-wise inclusion. We extend the notation to the collections of theory families of π -structures. Thus, given a π -structure $\mathcal{K} = \langle \mathbf{K}, D \rangle$, we define

$$\mathbf{ThFam}(\mathcal{K}) = \langle \mathbf{ThFam}(\mathcal{K}), \leq \rangle.$$

Theorem 896 *Let $\mathbf{K} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $(\alpha, \beta) : \mathcal{K} \rightleftarrows \mathcal{K}'$ a conjugate pair. Then*

$$\beta^* : \mathbf{ThFam}(\mathcal{K}) \rightarrow \mathbf{ThFam}(\mathcal{K}') \quad \text{and} \quad \alpha^* : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$$

are mutually inverse order isomorphisms.

Proof: We know, by Lemma 895, that β^* and α^* are mutually inverse bijections. Moreover, by definition, they are both order preserving. Thus, each is also order-reflecting, since, e.g., for all $S', T' \in \mathbf{ThFam}(\mathcal{K}')$,

$$\begin{aligned} \alpha^*(S') \leq \alpha^*(T') & \text{ implies } \beta^*(\alpha^*(S')) \leq \beta^*(\alpha^*(T')) \\ & \text{ implies } S' \leq T', \end{aligned}$$

the latter implication following by Lemma 894. ■

Conversely, it is true that given mutually inverse order isomorphisms between the complete lattices of two π -structures, one may define a conjugate pair between the two that establishes this order-isomorphism via the process that was described above. We provide, next, more details on this inverse process.

Let $\mathbf{K} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and

$$h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$$

an order isomorphism between the corresponding complete lattices of theory families.

Define $\vec{h} = \{ \vec{h}_\Sigma \}_{\Sigma \in |\mathbf{Sign}|}$ by letting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\vec{h}_\Sigma : \mathbf{SEN}(\Sigma) \rightarrow \mathbf{SenFam}(\mathbf{K}')$$

be given, for all $\phi \in \mathbf{SEN}(\Sigma)$, by

$$\vec{h}_\Sigma[\phi] = h^{-1}(D(\phi)).$$

Further, define $\overleftarrow{h} = \{ \overleftarrow{h}_{\Sigma'} \}_{\Sigma' \in |\mathbf{Sign}'|}$ by letting, for all $\Sigma' \in |\mathbf{Sign}'|$,

$$\overleftarrow{h}_{\Sigma'} : \mathbf{SEN}'(\Sigma') \rightarrow \mathbf{SenFam}(\mathbf{K})$$

be given, for all $\psi \in \text{SEN}'(\Sigma')$, by

$$\overleftarrow{h}_{\Sigma'}[\psi] = h(D'(\psi)).$$

We show that, the two translations $\overrightarrow{h} : \mathbf{K} \rightarrow \mathbf{K}'$ and $\overleftarrow{h} : \mathbf{K}' \rightarrow \mathbf{K}$, defined above, constitute interpretations between the corresponding π -structures.

Lemma 897 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ an order isomorphism. Then $\overleftarrow{h} : \mathcal{K}' \rightarrow \mathcal{K}$ is an interpretation.*

Proof: Suppose $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ is an order isomorphism and let $\Sigma' \in |\mathbf{Sign}'|$ and $\Psi \cup \{\psi\} \subseteq \text{SEN}'(\Sigma')$. Then we have

$$\begin{aligned} \psi \in D'_{\Sigma'}(\Psi) & \text{ iff } D'(\psi) \leq D'(\Psi) \quad (\text{Property of } D') \\ & \text{ iff } h(D'(\psi)) \leq h(D'(\Psi)) \quad (h \text{ order iso}) \\ & \text{ iff } h(D'(\psi)) \leq h(\bigvee^{\mathcal{K}'} \{D'(\chi) : \chi \in \Psi\}) \quad (\text{Property of } \bigvee^{\mathcal{K}'}) \\ & \text{ iff } h(D'(\psi)) \leq \bigvee^{\mathcal{K}} \{h(D'(\chi)) : \chi \in \Psi\} \quad (h \text{ order iso}) \\ & \text{ iff } \overleftarrow{h}_{\Sigma'}[\psi] \leq \bigvee^{\mathcal{K}} \{\overleftarrow{h}_{\Sigma'}[\chi] : \chi \in \Psi\} \quad (\text{Definition of } \overleftarrow{h}) \\ & \text{ iff } \overleftarrow{h}_{\Sigma'}[\psi] \leq D(\overleftarrow{h}_{\Sigma'}[\Psi]). \quad (\text{Property of } \bigvee^{\mathcal{K}}) \end{aligned}$$

Thus, $\overleftarrow{h} : \mathcal{K}' \rightarrow \mathcal{K}$ is indeed an interpretation. ■

We now know (by symmetry, based on Lemma 897) that $\overrightarrow{h} : \mathcal{K} \rightarrow \mathcal{K}'$ and $\overleftarrow{h} : \mathcal{K}' \rightarrow \mathcal{K}$ are interpretations. It is, in fact, the case that $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ forms a conjugate pair, as is shown next.

Lemma 898 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ an order isomorphism. Then $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair.*

Proof: By Lemma 892, it suffices to show that $\overleftarrow{h} : \mathcal{K}' \rightarrow \mathcal{K}$ is an interpretation and that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$D(\phi) = D(\overleftarrow{h}[\overrightarrow{h}_{\Sigma}[\phi]]).$$

The former has been shown in Lemma 897. So it suffices to show the latter.

To this end, let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$. Then we have

$$\begin{aligned}
 D(\overleftarrow{h}[\overrightarrow{h}_\Sigma[\phi]]) &= D(\overleftarrow{h}[h^{-1}(D(\phi))]) \quad (\text{Definition of } \overrightarrow{h}) \\
 &= D(\bigcup\{\overleftarrow{h}[\chi] : \chi \in h^{-1}(D(\phi))\}) \\
 &= \bigvee^{\mathcal{K}}\{\overleftarrow{h}[\chi] : \chi \in h^{-1}(D(\phi))\} \quad (\text{Property of } \bigvee^{\mathcal{K}}) \\
 &= \bigvee^{\mathcal{K}}\{h(D'(\chi)) : \chi \in h^{-1}(D(\phi))\} \quad (\text{Definition of } \overleftarrow{h}) \\
 &= h(\bigvee^{\mathcal{K}'}\{D'(\chi) : \chi \in h^{-1}(D(\phi))\}) \quad (h \text{ order iso}) \\
 &= h(D'(h^{-1}(D(\phi)))) \quad (\text{Property of } \bigvee^{\mathcal{K}'}) \\
 &= h(h^{-1}(D(\phi))) \quad (h^{-1}(D(\phi)) \text{ theory family}) \\
 &= D(\phi).
 \end{aligned}$$

We conclude that $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair. $\blacksquare$

Based on Lemma 898, we can now formulate one of the main theorems of this section to the effect that every order isomorphism between the complete lattices of theory families of two π -structures gives rise to a conjugate pair of interpretations that induce the isomorphism via the star construction.

Theorem 899 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{K}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathcal{K} = \langle \mathbf{K}, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}', D' \rangle$ be π -structures based on $\mathbf{K}$, $\mathbf{K}'$, respectively, and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ an order isomorphism. Then $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ is a conjugate pair, such that $\overrightarrow{h}^* = h$ and $\overleftarrow{h}^* = h^{-1}$.*

Proof: By Lemma 898, we know that $(\overrightarrow{h}, \overleftarrow{h}) : \mathcal{K} \rightleftarrows \mathcal{K}'$ forms a conjugate pair. We show that $\overrightarrow{h}^* = h$. The equality $\overleftarrow{h}^* = h^{-1}$ may be proved similarly. To this end, let $T' \in \text{ThFam}(\mathcal{K}')$. Then we have

$$\begin{aligned}
 \overrightarrow{h}_\Sigma^*(T') &= \{\phi \in \text{SEN}(\Sigma) : \overrightarrow{h}_\Sigma[\phi] \leq T'\} \quad (\text{Definition of } *) \\
 &= \{\phi \in \text{SEN}(\Sigma) : h^{-1}(D(\phi)) \leq T'\} \quad (\text{Definition of } \overrightarrow{h}) \\
 &= D_\Sigma(\{\phi \in \text{SEN}(\Sigma) : h^{-1}(D(\phi)) \leq T'\}) \\
 &= D_\Sigma(\{\phi \in \text{SEN}(\Sigma) : D(\phi) \leq h(T')\}) \quad (h \text{ order iso}) \\
 &= D_\Sigma(\{\phi \in \text{SEN}(\Sigma) : \phi \in h_\Sigma(T')\}) \quad (\text{Property of } D) \\
 &= D_\Sigma(h_\Sigma(T')) \\
 &= h_\Sigma(T'). \quad (h(T') \text{ theory family})
 \end{aligned}$$

Similarly, $\overleftarrow{h}^* = h^{-1}$. $\blacksquare$

12.3 Transformations

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $k \geq 1$ be an integer. Then a **power algebraic system**

$$\mathbf{K}^k = \langle \mathbf{Sign}, \text{SEN}^k, N^k \rangle$$

is the algebraic system whose sentence functor $\text{SEN}^k : \mathbf{Sign} \rightarrow \mathbf{Set}$ is the k -th direct power of SEN and whose category N^k of natural transformations consists of k -tuples of natural transformations having the same arity in N .

Let $k, \ell \geq 1$ be integers. A translation $\alpha : \mathbf{K}^k \rightarrow \mathbf{K}^\ell$ is called a **transformation** if there exists a set

$$\tau : \text{SEN}^\omega \rightarrow \text{SEN}^\ell,$$

in N , with k distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \text{SEN}(\Sigma)^k$,

$$\alpha_\Sigma[\vec{\phi}] = \tau_\Sigma[\vec{\phi}].$$

Moreover a translation $\alpha : \mathbf{K}^k \rightarrow \mathbf{K}^\ell$ is called a **natural transformation** if it is a parameter free transformation, i.e., if there exists $\tau : \text{SEN}^k \rightarrow \text{SEN}^\ell$ in N , such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \text{SEN}(\Sigma)^k$,

$$\alpha_\Sigma[\vec{\phi}] = \tau_\Sigma[\vec{\phi}].$$

Based on the results obtained in Section 12.2, we may formulate some propositions concerning interpretability and equivalence based on transformations.

Proposition 900 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{F}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures. $\mathcal{K}$ is interpretable in $\mathcal{K}'$ via a transformation if and only if there exists a set $\tau : \text{SEN}^\omega \rightarrow \text{SEN}^\ell$, with k distinguished arguments, such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\vec{\phi}\} \subseteq \text{SEN}(\Sigma)^k$,*

$$\vec{\phi} \in D_\Sigma(\Phi) \quad \text{iff} \quad \tau_\Sigma[\vec{\phi}] \leq D'(\tau_\Sigma[\Phi]).$$

If $\mathcal{K}$ is interpretable in $\mathcal{K}'$ as above, then it is equivalent to $\mathcal{K}'$ via a conjugate pair $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ of transformations if and only if, for all $\Sigma \in |\mathbf{Sign}|$, all $\vec{\phi} \in \text{SEN}(\Sigma)^k$ and all $\Psi \cup \{\vec{\psi}\} \subseteq \text{SEN}(\Sigma)^\ell$,

- $\vec{\psi} \in D'_\Sigma(\Psi)$ iff $I_\Sigma[\vec{\psi}] \leq D(I_\Sigma[\Psi]);$
- $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]]);$
- $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: This is a restatement of the definition of interpretability under the additional hypothesis that the corresponding interpretations are transformations. ■

Proposition 901 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures. $\mathcal{K}$ is equivalent to $\mathcal{K}'$ via a conjugate pair $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ of transformations if and only if one of the following equivalent conditions hold:*

- (a) $\tau : \mathcal{K} \rightarrow \mathcal{K}'$ is an interpretation and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\psi} \in \text{SEN}(\Sigma)^\ell$, $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;
- (b) $I : \mathcal{K}' \rightarrow \mathcal{K}$ is an interpretation and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \text{SEN}(\Sigma)^k$, $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: Directly by Lemma 892. ■

Taking the point of view of order isomorphisms between lattices of theory families, we would like to have a concept ensuring that such an isomorphism is induced not merely by a conjugate pair of translations, as is asserted by Theorem 899, but, more emphatically, by a conjugate pair of transformations. We focus on this task next.

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures based on $\mathbf{K}^k$, $\mathbf{K}^\ell$, respectively. An order isomorphism $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ is called **transformational** if there exist sets

- $\tau : \text{SEN}^\omega \rightarrow \text{SEN}^\ell$ in N , with k distinguished arguments;
- $I : \text{SEN}^\omega \rightarrow \text{SEN}^k$ in N , with ℓ distinguished arguments,

such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \text{SEN}(\Sigma)^k$ and all $\vec{\psi} \in \text{SEN}(\Sigma)^\ell$,

$$\vec{h}_\Sigma[\vec{\phi}] = D'(\tau_\Sigma[\vec{\phi}]) \quad \text{and} \quad \overleftarrow{h}_\Sigma[\vec{\psi}] = D(I_\Sigma[\vec{\psi}]).$$

These conditions are, by definition, equivalent, respectively, to the conditions

$$h^{-1}(D(\vec{\phi})) = D'(\tau_\Sigma[\vec{\phi}]) \quad \text{and} \quad h(D'(\vec{\psi})) = D(I_\Sigma[\vec{\psi}]).$$

In this case, we say that h is **induced by** $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$. (Note that, since we will be able to show that (τ, I) is a conjugate pair of transformations, this notation makes sense.)

In fact, the defining conditions yield some crucial relations between theory families, as is shown in the following lemma.

Lemma 902 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ a transformational order isomorphism induced by $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$. Then, for all $\Sigma \in |\mathbf{Sign}|$, all $\Phi \subseteq \text{SEN}(\Sigma)^k$ and all $\Psi \subseteq \text{SEN}(\Sigma)^\ell$,*

$$h^{-1}(D(\Phi)) = D'(\tau_\Sigma[\Phi]) \quad \text{and} \quad h(D'(\Psi)) = D(I_\Sigma[\Psi]).$$

Proof: By symmetry, it suffices to show the first equation. We have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)^k$,

$$\begin{aligned} h^{-1}(D(\Phi)) &= h^{-1}(\bigvee_{\phi \in \Phi}^{\mathcal{K}} D(\phi)) \quad (\text{join in } \mathbf{ThFam}(\mathcal{K})) \\ &= \bigvee_{\phi \in \Phi}^{\mathcal{K}'} h^{-1}(D(\phi)) \quad (h^{-1} \text{ order isomorphism}) \\ &= \bigvee_{\phi \in \Phi}^{\mathcal{K}'} D'(\tau_\Sigma[\phi]) \quad (h^{-1}(D(\phi)) = \vec{h}_\Sigma[\phi]) \\ &= D'(\bigcup_{\phi \in \Phi} \tau_\Sigma[\phi]) \quad (\text{join in } \mathbf{ThFam}(\mathcal{K}')) \\ &= D'(\tau_\Sigma[\Phi]). \quad (\text{by definition}) \end{aligned}$$

The second equation now follows by symmetry. $\blacksquare$

Now we are in a position to show that a transformational order isomorphism between the lattices of theory families of two π -structures is induced by a conjugate pair of transformations between the two π -structures and, as a consequence, gives rise to an equivalence $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$ via a conjugate pair of transformations.

Theorem 903 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ a transformational order isomorphism induced by $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$. Then $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$ is a conjugate pair of transformations.*

Proof: We use Proposition 901. Let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\vec{\phi}\} \subseteq \text{SEN}(\Sigma)^k$ and $\vec{\psi} \in \text{SEN}(\Sigma)^\ell$. We then have:

$$\begin{aligned} \vec{\phi} \in D_\Sigma(\Phi) & \text{ iff } D_\Sigma(\vec{\phi}) \leq D_\Sigma(\Phi) \quad (\text{Property of } D) \\ & \text{ iff } h^{-1}(D(\vec{\phi})) \leq h^{-1}(D(\Phi)) \quad (h \text{ order iso}) \\ & \text{ iff } D'(\tau_\Sigma[\vec{\phi}]) \leq D'(\tau_\Sigma[\Phi]) \quad (\text{Lemma 902}) \\ & \text{ iff } \tau_\Sigma[\vec{\phi}] \leq D'(\tau_\Sigma[\Phi]). \quad (\text{Property of } D') \end{aligned}$$

Thus, $\tau : \mathcal{K} \rightarrow \mathcal{K}'$ is an interpretation. Moreover, we have:

$$\begin{aligned} D'(\vec{\psi}) &= h^{-1}(h(D'(\vec{\psi}))) \quad (h \text{ order isomorphism}) \\ &= h^{-1}(D(I_\Sigma[\vec{\psi}])) \quad (h \text{ transformational}) \\ &= D'(\tau[I_\Sigma[\vec{\psi}]]) \quad (\text{Lemma 902}) \end{aligned}$$

We conclude by Proposition 901, that $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$ is a conjugate pair of transformations. $\blacksquare$

As a consequence, we have the following

Theorem 904 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ a transformational order isomorphism induced by $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$. Then the π -structures $\mathcal{K}$ and $\mathcal{K}'$ are equivalent via the conjugate pair $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$ of transformations.*

Proof: This follows directly by Theorem 903. $\blacksquare$

Similarly, for interpretability and equivalence based on natural transformations, we have the following corresponding propositions.

Proposition 905 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures. $\mathcal{K}$ is interpretable in $\mathcal{K}'$ via a natural transformation if and only if there exists a set $\tau : \text{SEN}^k \rightarrow \text{SEN}^\ell$ in N , such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\vec{\phi}\} \subseteq \text{SEN}(\Sigma)^k$,*

$$\vec{\phi} \in D_\Sigma(\Phi) \quad \text{iff} \quad \tau_\Sigma[\vec{\phi}] \leq D'(\tau_\Sigma[\Phi]).$$

If $\mathcal{K}$ is interpretable in $\mathcal{K}'$ as above, then it is equivalent to $\mathcal{K}'$ via a conjugate pair $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ of natural transformations if and only if, for all $\Sigma \in |\mathbf{Sign}|$, all $\vec{\phi} \in \text{SEN}(\Sigma)^k$ and all $\Psi \cup \{\vec{\psi}\} \subseteq \text{SEN}(\Sigma)^\ell$,

- $\vec{\psi} \in D'_\Sigma(\Psi)$ iff $I_\Sigma[\vec{\psi}] \leq D(I_\Sigma[\Psi])$;
- $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;
- $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: This is a restatement of the definition of interpretability under the additional hypothesis that the corresponding interpretations are natural transformations. ■

Proposition 906 Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures. $\mathcal{K}$ is equivalent to $\mathcal{K}'$ via a conjugate pair $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$ of natural transformations if and only if one of the following equivalent conditions hold:

- (a) $\tau : \mathcal{K} \rightarrow \mathcal{K}'$ is an interpretation and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\psi} \in \text{SEN}(\Sigma)^\ell$, $D'(\vec{\psi}) = D'(\tau[I_\Sigma[\vec{\psi}]])$;
- (b) $I : \mathcal{K}' \rightarrow \mathcal{K}$ is an interpretation and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \text{SEN}(\Sigma)^k$, $D(\vec{\phi}) = D(I[\tau_\Sigma[\vec{\phi}]])$.

Proof: Directly by Lemma 892. ■

In terms of order isomorphisms between lattices of theory families, we have analogs of preceding results that allow us to work with isomorphisms that are induced by conjugate pairs of natural transformations.

Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures based on $\mathbf{K}^k$, $\mathbf{K}^\ell$, respectively. An order isomorphism $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ is called **natural** if there exist sets

- $\tau : \text{SEN}^k \rightarrow \text{SEN}^\ell$ in N ;
- $I : \text{SEN}^\ell \rightarrow \text{SEN}^k$ in N ,

such that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi} \in \text{SEN}(\Sigma)^k$ and $\vec{\psi} \in \text{SEN}(\Sigma)^\ell$,

$$\vec{h}_\Sigma[\vec{\phi}] = D'(\tau_\Sigma[\vec{\phi}]) \quad \text{and} \quad \overleftarrow{h}_\Sigma[\vec{\psi}] = D(I_\Sigma[\vec{\psi}]).$$

In this case, we say that h is **induced by** the pair of natural transformations $(\tau, I) : \mathcal{K} \rightleftarrows \mathcal{K}'$.

Similarly, with the case of a transformational isomorphism, we can show that a natural order isomorphism between the lattices of theory families of two π -structures is induced by a conjugate pair of natural transformations between the two π -structures.

Theorem 907 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ a natural order isomorphism induced by $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$. Then $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$ is a conjugate pair of natural transformations.*

Proof: This follows from Theorem 903. ■

As a consequence, we have the following analog of Theorem 904.

Theorem 908 *Let $\mathbf{K} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathcal{K} = \langle \mathbf{K}^k, D \rangle$, $\mathcal{K}' = \langle \mathbf{K}^\ell, D' \rangle$ be two π -structures and $h : \mathbf{ThFam}(\mathcal{K}') \rightarrow \mathbf{ThFam}(\mathcal{K})$ a natural order isomorphism induced by $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$. Then the π -structures $\mathcal{K}$ and $\mathcal{K}'$ are equivalent via the conjugate pair $(\tau, I) : \mathcal{K} \rightleftharpoons \mathcal{K}'$ of natural transformations.*

Proof: This follows directly by Theorem 907. ■

We now revert to the case of a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ and a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$. Our focus, in this standard context, will be on $\mathbf{F}$ itself, on the one hand, and on $\mathbf{F}^2$, on the other. In the context of $\mathbf{F}^2$, given $\Sigma \in |\mathbf{Sign}^b|$, we sometimes denote a pair $\langle \phi, \psi \rangle \in \text{SEN}^b(\Sigma)^2$ in the equational form

$$\phi \approx \psi.$$

Given a π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$, we say that $\mathcal{Q}$ is **equational** if the following five axioms hold:

- (R) $\phi \approx \phi \in D_\Sigma(\emptyset)$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$;
- (S) $\psi \approx \phi \in D_\Sigma(\phi \approx \psi)$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$;
- (T) $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi)$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$;
- (C) $\sigma_\Sigma^b(\vec{\phi}) \approx \sigma_\Sigma^b(\vec{\psi}) \in D_\Sigma(\{\phi_i \approx \psi_i : i < k\})$, for all $\sigma^b \in N^b$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_i, \psi_i \in \text{SEN}^b(\Sigma)$, $i < k$;
- (I) $\text{SEN}^b(f)(\phi) \approx \text{SEN}^b(f)(\psi) \in D_{\Sigma'}(\phi \approx \psi)$, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$.

Note that according to the relevant definitions introduced in Chapter 2, the meaning of (I) is that the Σ' -component of the least theory family including $\phi \approx \psi$ in its Σ -component includes $\text{SEN}^b(f)(\phi) \approx \text{SEN}^b(f)(\psi)$.

These properties are called **reflexivity**, **symmetry**, **transitivity**, **compatibility** and **invariance**, respectively. The first three ensure that, for all $E \in \text{SenFam}(\mathbf{F}^2)$, $D(E)$ is an equivalence family. The fourth ensures that $D(E)$ is a congruence family and the last that it is a congruence system, i.e., invariant under the action of signature morphisms. In fact, the following characterization theorem holds, showing that a π -structure is equational if

and only if it is structural and all its closure families are congruence systems on $\mathbf{F}$ if and only if it is the equational π -structure relative to a class $\mathbf{K}$ of $\mathbf{F}$ -algebraic systems according to the definition given in Section 2.17.

Theorem 909 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ a π -structure. The following statements are equivalent:*

- (i) $\mathcal{Q}$ is equational;
- (ii) For all $\theta \in \text{SenFam}(\mathcal{Q})$, $D(\theta) \in \text{ConSys}(\mathbf{F})$;
- (iii) For some class $\mathbf{K}$ of $\mathbf{F}$ -algebraic systems, $D = D^{\mathbf{K}}$.

Proof:

(i) $\Rightarrow$ (ii) Suppose $\mathcal{Q}$ is equational and let $\theta \in \text{SenFam}(\mathcal{Q})$. We must show that $D(\theta) = \{D_{\Sigma}(\theta)\}_{\Sigma \in |\mathbf{Sign}^b|}$ is a congruence system on $\mathbf{F}$. To this end, let $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$. Since $\mathcal{Q}$ is equational, we have $\phi \approx \phi \in D_{\Sigma}(\emptyset) \subseteq D_{\Sigma}(\theta)$. So $D_{\Sigma}(\theta)$ is reflexive. Suppose, next, that $\phi \approx \psi \in D_{\Sigma}(\theta)$. Since $\mathcal{Q}$ is equational, we get $\psi \approx \phi \in D_{\Sigma}(\phi \approx \psi) \subseteq D_{\Sigma}(\theta)$. Hence, $D_{\Sigma}(\theta)$ is also symmetric. Further, if $\phi \approx \psi, \psi \approx \chi \in D_{\Sigma}(\theta)$, then, since $\mathcal{Q}$ is equational, we get $\phi \approx \chi \in D_{\Sigma}(\phi \approx \psi, \psi \approx \chi) \subseteq D_{\Sigma}(\theta)$. Thus, $D_{\Sigma}(\theta)$ is also transitive and, hence, an equivalence relation on $\mathbf{SEN}^b(\Sigma)$.

Suppose, now, that $\sigma^b \in N^b$, $\phi_i, \psi_i \in \mathbf{SEN}^b(\Sigma)$, for $i < k$, such that $\phi_i \approx \psi_i \in D_{\Sigma}(\theta)$, for all $i < k$. Since $\mathcal{Q}$ is equational, we get $\sigma_{\Sigma}^b(\vec{\phi}) \approx \sigma_{\Sigma}^b(\vec{\psi}) \in D_{\Sigma}(\{\phi_i \approx \psi_i : i < k\}) \subseteq D_{\Sigma}(\theta)$. Hence, $D_{\Sigma}(\theta)$ is a congruence family on $\mathbf{F}$. Finally, if $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \approx \psi \in D_{\Sigma}(\theta)$, then, again based on the fact that $\mathcal{Q}$ is equational, we obtain $\mathbf{SEN}^b(f)(\phi) \approx \mathbf{SEN}^b(f)(\psi) \in D_{\Sigma'}(\phi \approx \psi) \subseteq D_{\Sigma'}(\theta)$, whence $D(\theta)$ is a congruence system on $\mathbf{F}$, as was to be shown.

(ii) $\Rightarrow$ (iii) Suppose D satisfies (ii). We construct a class $\mathbf{K}$ of $\mathbf{F}$ -algebraic systems as follows. For $\theta \in \text{SenFam}(\mathcal{Q})$, define

$$\mathcal{F}^{\theta} = \langle \mathbf{F}^{\theta}, \langle I, \pi^{\theta} \rangle \rangle := \langle \mathbf{F}/D(\theta), \langle I, \pi^{D(\theta)} \rangle \rangle$$

and set

$$\mathbf{K} = \{\mathcal{F}^{\theta} : \theta \in \text{SenFam}(\mathcal{Q})\}.$$

Note that the definition of $\mathcal{F}^{\theta}$ makes sense, since, by hypothesis, $D(\theta) \in \text{ConSys}(\mathbf{F})$, for all $\theta \in \text{SenFam}(\mathcal{Q})$. Our task now is to show that $D = D^{\mathbf{K}}$. To this end, let $\Sigma \in |\mathbf{Sign}^b|$, $\theta \cup \{\phi \approx \psi\} \subseteq \mathbf{SEN}^b(\Sigma)^2$.

Suppose, first, that $\phi \approx \psi \in D_{\Sigma}(\theta)$ and let $\theta' \in \text{SenFam}(\mathcal{Q})$, such that $\pi_{\Sigma}^{\theta'}(\theta) \subseteq \Delta_{\Sigma}^{\mathbf{F}/D(\theta')}$. This is equivalent to $\theta_{\Sigma} \subseteq D_{\Sigma}(\theta'_{\Sigma})$. Hence, we obtain

$\phi \approx \psi \in D_\Sigma(\theta) \subseteq D_\Sigma(\theta')$. Thus, $\pi_\Sigma^{\theta'}(\phi) = \pi_\Sigma^{\theta'}(\psi)$. We conclude that $\phi \approx \psi \in D_\Sigma^K(\theta)$. Hence, $D \leq D^K$.

Assume, conversely, that $\phi \approx \psi \notin D_\Sigma(\theta)$. Then, clearly, for $\mathcal{F}^\theta \in \mathbf{K}$, we get $\pi_\Sigma^\theta(D_\Sigma(\theta)) \subseteq \Delta_\Sigma^{\mathbf{F}/D(\theta)}$, but $\pi_\Sigma^\theta(\phi) \neq \pi_\Sigma^\theta(\psi)$. Hence, $\phi \approx \psi \notin D_\Sigma^K(\theta)$. Therefore, $D^K \leq D$ and, hence, $D = D^K$.

(iii) $\Rightarrow$ (i) This implication was shown in Proposition 115, which was proven by appealing to the implication (iii) $\Rightarrow$ (ii), which was, in turn, the content of Proposition 30. ■

We have the following useful technical lemma, where, for $\Sigma \in |\mathbf{Sign}^b|$ and $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$, we use the abbreviation

$$\vec{\phi} \approx \vec{\psi} = \{\phi_i \approx \psi_i : i < k\}.$$

Lemma 910 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ an equational π -structure. Then, for all $\delta^b, \epsilon^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$,*

$$\delta_\Sigma^b(\vec{\psi}) \approx \epsilon_\Sigma^b(\vec{\psi}) \in D_\Sigma(\vec{\phi} \approx \vec{\psi}, \delta_\Sigma^b(\vec{\phi}) \approx \epsilon_\Sigma^b(\vec{\phi})).$$

Proof: We have, for all $\delta^b, \epsilon^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \delta_\Sigma^b(\vec{\psi}) \approx \epsilon_\Sigma^b(\vec{\psi}) &\in D_\Sigma(\delta_\Sigma^b(\vec{\psi}) \approx \delta_\Sigma^b(\vec{\phi}), \delta_\Sigma^b(\vec{\phi}) \approx \epsilon_\Sigma^b(\vec{\phi}), \epsilon_\Sigma^b(\vec{\phi}) \approx \epsilon_\Sigma^b(\vec{\psi})) \\ &\quad (\text{by transitivity}) \\ &\subseteq D_\Sigma(\vec{\phi} \approx \vec{\psi}, \delta_\Sigma^b(\vec{\phi}) \approx \epsilon_\Sigma^b(\vec{\phi})). \\ &\quad (\text{by symmetry and compatibility}) \end{aligned}$$

This proves the lemma. ■

Lemma 910 has the following corollary.

Corollary 911 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ an equational π -structure. Then, for all $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with k distinguished arguments, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$,*

$$\tau_\Sigma^b[\vec{\psi}] \leq D(\vec{\phi} \approx \vec{\psi}, \tau_\Sigma^b[\vec{\phi}]).$$

Proof: This follows from Lemma 910, using the reflexivity and the invariance of the closure family D . ■

We next show that, if a π -institution $\mathcal{I}$, based on an algebraic system $\mathbf{F}$, happens to be equivalent to an equational π -structure $\mathcal{Q}$, based on $\mathbf{F}^2$, via a conjugate pair $(\tau, I) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is syntactically protoalgebraic with set of witnessing transformations I .

Theorem 912 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ an equational π -structure. If $\mathcal{I}$ is equivalent to $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations I^b .*

Proof: By definition, it suffices to show that $I^b : \mathbf{SEN}^\omega \rightarrow \mathbf{SEN}$, with two distinguished arguments, is reflexive, globally family transitive and has the global family compatibility and the global family modus ponens in $\mathcal{I}$. To this end, let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$. Then we have, in turn:

- By reflexivity of $\mathcal{Q}$, $\phi \approx \phi \in D_\Sigma(\emptyset)$. Hence, by interpretability, we get $I_\Sigma^b[\phi, \phi] \leq C(\emptyset)$. Therefore, I^b is reflexive in $\mathcal{I}$;
- By transitivity of $\mathcal{Q}$, $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi)$. Hence, by interpretability, we get $I_\Sigma^b[\phi, \chi] \leq C(I_\Sigma^b[\phi, \psi], I_\Sigma^b[\psi, \chi])$. Therefore, I^b is globally family transitive in $\mathcal{I}$;
- By the reflexivity and compatibility of $\mathcal{Q}$, we have, for all $\sigma^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ in N and all $\tilde{\chi} \in \mathbf{SEN}^b(\Sigma)$, that $\sigma_\Sigma^b(\phi, \tilde{\chi}) \approx \sigma_\Sigma^b(\psi, \tilde{\chi}) \in D_\Sigma(\phi \approx \psi)$. Hence, by interpretability,

$$I_\Sigma^b[\sigma_\Sigma^b(\phi, \tilde{\chi}), \sigma_\Sigma^b(\psi, \tilde{\chi})] \leq C(I_\Sigma^b[\phi, \psi]).$$

Therefore, I^b has the global family compatibility in $\mathcal{I}$;

- Finally, for global family MP, we have

$$\begin{aligned} C(\psi) &= C(I_\Sigma^b[\tau_\Sigma^b[\psi]]) \quad (\text{by equivalence}) \\ &\leq C(I_\Sigma^b[\phi, \psi], I_\Sigma^b[\tau_\Sigma^b[\phi]]) \\ &\quad (\text{by Lemma 910 and interpretability}) \\ &= C(I_\Sigma^b[\phi, \psi], \phi). \quad (\text{by equivalence}) \end{aligned}$$

Thus, for all $T \in \text{ThFam}(\mathcal{I})$, if $\phi \in T_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq T$, then $\psi \in T_\Sigma$, i.e., I^b has the global family modus ponens in $\mathcal{I}$.

We conclude that $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations I^b . ■

Using Theorem 912, we can show that, if a π -institution $\mathcal{I}$, based on an algebraic system $\mathbf{F}$, happens to be equivalent to an equational π -structure $\mathcal{Q}$, based on $\mathbf{F}^2$, via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is family truth equational, with witnessing equations τ^b .

Theorem 913 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ an equational π -structure. If $\mathcal{I}$ is equivalent to $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is family truth equational, with witnessing equations τ^b .*

Proof: By definition, it suffices to show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

We, indeed, have, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in T_\Sigma & \quad \text{iff} \quad I^b[\tau_\Sigma[\phi]] \leq T \quad ((\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q} \text{ an equivalence}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T). \quad (\text{by Theorem 912 and Corollary 791}) \end{aligned}$$

Therefore, $\mathcal{I}$ is family truth equational, with witnessing equations τ^b . ■

We close the section by showing that equivalence between a given π -institution and an equational π -structure established via conjugate pairs of transformations is essentially unique in the sense that both the closure family on $\mathbf{F}^2$ must be unique and the closures of the translations used must be identical. More precisely, we have the following

Theorem 914 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Suppose that $\mathcal{Q}^1 = \langle \mathbf{F}^2, D^1 \rangle$ and $\mathcal{Q}^2 = \langle \mathbf{F}^2, D^2 \rangle$ are equational π -structures that are equivalent to $\mathcal{I}$ via the conjugate pairs $\langle \tau^1, I^1 \rangle : \mathcal{I} \rightleftarrows \mathcal{Q}^1$ and $\langle \tau^2, I^2 \rangle : \mathcal{I} \rightleftarrows \mathcal{Q}^2$, respectively, of transformations. Then, we have:*

- (a) $D^1 = D^2$ ($=: D$) and, hence, $\mathcal{Q}^1 = \mathcal{Q}^2$ ($=: \mathcal{Q}$);
- (b) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $C(I_\Sigma^1[\phi, \psi]) = C(I_\Sigma^2[\phi, \psi])$;
- (c) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $D(\tau_\Sigma^1[\phi]) = D(\tau_\Sigma^2[\phi])$.

Proof: By Theorem 912, we know that both I^1 and I^2 are witnessing the syntactic protoalgebraicity of $\mathcal{I}$. Thus, by Corollary 791, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$I_\Sigma^1[\phi, \psi] \leq T \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad I_\Sigma^2[\phi, \psi] \leq T.$$

We conclude that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $C(I_\Sigma^1[\phi, \psi]) = C(I_\Sigma^2[\phi, \psi])$, which proves Part (b).

For Part (a), suppose that $\Sigma \in |\mathbf{Sign}^b|$ and $E \cup \{\phi \approx \psi\} \subseteq \text{SEN}^b(\Sigma)^2$. Then, we have

$$\begin{aligned} \phi \approx \psi \in D_\Sigma^1(E) & \quad \text{iff} \quad I_\Sigma^1[\phi, \psi] \leq C(I_\Sigma^1[E]) \quad (\text{interpretability}) \\ & \quad \text{iff} \quad C(I_\Sigma^1[\phi, \psi]) \leq C(I_\Sigma^1[E]) \quad (\text{property of } C) \\ & \quad \text{iff} \quad C(I_\Sigma^2[\phi, \psi]) \leq C(I_\Sigma^2[E]) \quad (\text{Part (b)}) \\ & \quad \text{iff} \quad I_\Sigma^2[\phi, \psi] \leq C(I_\Sigma^2[E]) \quad (\text{property of } C) \\ & \quad \text{iff} \quad \phi \approx \psi \in D_\Sigma^2(E). \quad (\text{interpretability}) \end{aligned}$$

Therefore, we get that $D^1 = D^2$. This justifies using $D := D^1 = D^2$ and since the π -structures $\mathcal{Q}^1$ and $\mathcal{Q}^2$, which are both based on $\mathbf{F}^2$, have the same closure families, we obtain $\mathcal{Q} := \mathcal{Q}^1 = \mathcal{Q}^2$.

Finally, for Part (c), suppose that $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then, we have

$$\begin{aligned}
 D(\tau_\Sigma^1[\phi]) \leq D(\tau_\Sigma^2[\phi]) & \text{ iff } \tau_\Sigma^1[\phi] \leq D(\tau_\Sigma^2[\phi]) \quad (\text{property of } D) \\
 & \text{ iff } I^2[\tau_\Sigma^1[\phi]] \leq C(I^2[\tau_\Sigma^2[\phi]]) \quad (\text{interpretability}) \\
 & \text{ iff } I^2[\tau_\Sigma^1[\phi]] \leq C(\phi) \quad (\text{equivalence}) \\
 & \text{ iff } I^1[\tau_\Sigma^1[\phi]] \leq C(\phi) \quad (\text{Part (b)}) \\
 & \text{ iff } \phi \in C_\Sigma(\phi). \quad (\text{equivalence})
 \end{aligned}$$

By symmetry, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $D(\tau_\Sigma^1[\phi]) = D(\tau_\Sigma^2[\phi])$. This proves Part (c) and concludes the proof of the theorem. ■

12.4 Syntactic Weak Family Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 4, Section 4.3, that a π -institution is weakly family algebraizable (WF algebraizable) if it is protoalgebraic and family injective. We work now towards establishing a syntactic counterpart of this class of π -institutions.

We say that $\mathcal{I}$ is $R^\mathcal{I}S^\mathcal{I}$ -(**syntactically**) **fortified** if:

- The reflexive core $R^\mathcal{I}$ is Leibniz;
- The Suszko core $S^\mathcal{I}$ is adequate.

Moreover, we say that $\mathcal{I}$ is **syntactically weakly family algebraizable** (abbreviated to **syntactically WF algebraizable**) if:

- $\mathcal{I}$ is $R^\mathcal{I}S^\mathcal{I}$ -fortified;
- $\mathcal{I}$ is protoalgebraic;
- $\mathcal{I}$ is family injective.

By Theorem 288, under protoalgebraicity, the properties of family injectivity, family reflectivity and family c-reflectivity coincide. This enables us to formulate the following alternative characterization of syntactic WF algebraizability.

Theorem 915 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WF algebraizable if and only if it is syntactically protoalgebraic and family truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically WF algebraizable. Then, on the one hand, it is protoalgebraic and has a Leibniz reflexive core. Thus, by Theorem 805, it is syntactically protoalgebraic. On the other, it is, by Theorem 288, family c-reflective and has an adequate Suszko core. Therefore, by Theorem 848, it is family truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically protoalgebraic and family truth equational. Then, by Theorem 805, it is protoalgebraic and has a Leibniz reflexive core, and, by Theorem 848, it is family c-reflective and has an adequate Suszko core. Therefore, $\mathcal{I}$ is syntactically WF algebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic WF algebraizability classes of π -institutions.

Theorem 916 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WF algebraizable if and only if $\mathcal{I}$ is WF algebraizable and $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified.*

Proof: $\mathcal{I}$ is syntactically WF algebraizable if and only if, by definition, it is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified, protoalgebraic and family injective, i.e., iff it is, by definition, $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and WF algebraizable. ■

Previous results, put together, also allow us to provide an alternative characterization of syntactic weak family algebraizability in terms of isomorphisms between complete lattices of theory families.

Theorem 917 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WF algebraizable if and only if it is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: We have that $\mathcal{I}$ is syntactically WF algebraizable if and only if, by Theorem 916, it is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and WF algebraizable, if and only if, by Theorem 296, it is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. ■

Next, we show that syntactic WF algebraizability may also be characterized by the existence of an equivalence between the π -institution and its algebraic π -structure counterpart via a pair of conjugate transformations.

We embark on the path by defining first the algebraic π -structure $\mathcal{Q}^{\mathcal{I}*}$ associated with a given π -institution $\mathcal{I}$. We recall some concepts that we have already introduced previously which culminate in the definition of $\mathcal{Q}^{\mathcal{I}*}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall the definition of the class $\text{AlgSys}^*(\mathcal{I})$ of all reduced $\mathbf{F}$ -algebraic systems:

$$\text{AlgSys}^*(\mathcal{I}) = \{ \mathcal{A} : (\exists T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}) \}.$$

Given an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, we define the class of $\mathcal{I}^*$ -**congruence systems on $\mathcal{A}$** by

$$\text{ConSys}^{\mathcal{I}^*}(\mathcal{A}) = \{ \theta \in \text{ConSys}(\mathbf{A}) : \mathcal{A}/\theta \in \text{AlgSys}^*(\mathcal{I}) \}.$$

It turns out that congruence systems in $\text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ have a straightforward characterization.

Proposition 918 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\text{ConSys}^{\mathcal{I}^*}(\mathcal{A}) = \{ \theta \in \text{ConSys}(\mathbf{A}) : (\exists T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \theta) \}.$$

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system.

Suppose, first, that $\theta \in \text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. By definition, $\mathcal{A}/\theta \in \text{AlgSys}^*(\mathcal{I})$. Thus, there exists $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$, such that

$$\Omega^{\mathcal{A}/\theta}(T') = \Delta^{\mathcal{A}/\theta}.$$

By applying the inverse of the quotient morphism $\langle I, \pi^\theta \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$, we get

$$(\pi^\theta)^{-1}(\Omega^{\mathcal{A}/\theta}(T')) = (\pi^\theta)^{-1}(\Delta^{\mathcal{A}/\theta}).$$

Since $\langle I, \pi^\theta \rangle$ is surjective, we get by Proposition 24 and by Corollary 55, that $(\pi^\theta)^{-1}(T') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and

$$\Omega^{\mathcal{A}}((\pi^\theta)^{-1}(T')) = \theta.$$

Therefore, there exists $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \theta$.

Suppose, conversely, that $\theta \in \text{ConSys}(\mathbf{A})$, with $\Omega^{\mathcal{A}}(T) = \theta$, for some $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, we have $\Omega^{\mathcal{A}/\theta}(T/\theta) = \Delta^{\mathcal{A}/\theta}$ and, therefore, by definition, $\mathcal{A}/\theta \in \text{AlgSys}^*(\mathcal{I})$, implying that $\theta \in \text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. ■

In general, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ and an $\mathbf{F}$ -algebraic system $\mathcal{A}$, the family $\text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ of $\mathcal{I}^*$ -congruence systems on $\mathcal{A}$ need not be closed under signature-wise intersections, i.e., may not form a closure family on $\mathbf{A}^2$. However, we can show that, if $\mathcal{I}$ is protoalgebraic, this is always the case.

Proposition 919 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ is closed under arbitrary intersections and, therefore, forms a closure family on $\mathbf{A}^2$.*

Proof: First, note that $\text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ has a top element $\nabla^{\mathcal{A}}$. To see this, observe that $\mathcal{A}/\nabla^{\mathcal{A}}$ is a trivial algebraic system, which is always a member of $\text{AlgSys}^*(\mathcal{I})$.

It suffices now to show that $\text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ is closed under arbitrary intersections. To this end, suppose $\theta^i \in \text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$, for $i \in I$. By Proposition 918, for all $i \in I$, there exists $T^i \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T^i) = \theta^i$. But, by Lemma 23 and protoalgebraicity, we get that

$$\Omega^{\mathcal{A}}\left(\bigcap_{i \in I} T^i\right) = \bigcap_{i \in I} \Omega^{\mathcal{A}}(T^i) = \bigcap_{i \in I} \theta^i.$$

Now, again by Proposition 918, we conclude that $\bigcap_{i \in I} \theta^i \in \text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$. ■

Applying Proposition 919 to the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \rightarrow \mathbf{F}$ is the identity morphism, we get the following

Corollary 920 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Then, $\text{ConSys}^{\mathcal{I}^*}(\mathcal{F})$ is closed under arbitrary intersections and, therefore, forms a closure family on $\mathbf{F}^2$.*

Proof: This is a special case of Proposition 919. ■

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π -institution. We define, in accordance with Corollary 920, the **equational** or **algebraic π -structure $\mathcal{Q}^{\mathcal{I}^*}$ associated with $\mathcal{I}$** to be the π -structure

$$\mathcal{Q}^{\mathcal{I}^*} = \langle \mathbf{F}^2, D^{\mathcal{I}^*} \rangle,$$

where $D^{\mathcal{I}^*}$ is the closure (operator) family corresponding to the closure family $\text{ConSys}^{\mathcal{I}^*}(\mathcal{F})$.

Our first result in connecting syntactic WF algebraizability with the associated equational π -structure shows that, if a π -institution is syntactically WF algebraizable, then it is equivalent to its associated equational π -structure via a conjugate pair of transformations.

Theorem 921 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically WF algebraizable π -institution based on $\mathbf{F}$. Then $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair $(\tau^b, \overset{\leftrightarrow}{I}^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}^*}$ of transformations. More precisely:*

- $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, is a set of witnessing transformations of the syntactic protoalgebraicity of $\mathcal{I}$;
- $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$, with a single distinguished argument, is a set of witnessing equations for the family truth equationality of $\mathcal{I}$.

Proof: Suppose that $\mathcal{I}$ is syntactically WF algebraizable. Then, by Theorem 915, $\mathcal{I}$ is syntactically protoalgebraic and family truth equational. Therefore, there exist a set $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ of natural transformations in N^b , with two distinguished arguments, witnessing the syntactic protoalgebraicity of $\mathcal{I}$, and a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with a single distinguished argument, witnessing family truth equationality. To verify the conclusion, observe, first, that $\tau_\Sigma^b : \text{SEN}^b(\Sigma) \rightarrow \text{SenFam}(\mathbf{F}^2)$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, as the sentence family $\tau_\Sigma^b[\phi]$ and $\vec{I}_\Sigma^b : \text{SEN}^b(\Sigma)^2 \rightarrow \text{SenFam}(\mathbf{F})$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, as the sentence family $\vec{I}_\Sigma^b[\phi, \psi]$ are as required. Therefore, by Proposition 901, it suffices to show that:

(a) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq D^{\mathcal{I}*}(\tau_\Sigma^b[\Phi]);$$

(b) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^b[\vec{I}_\Sigma^b[\phi, \psi]]).$$

For (a), let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. Note that, for all $T \in \text{ThFam}(\mathcal{I})$, we have, by family truth equationality,

$$\begin{aligned} \Phi \subseteq T_\Sigma & \quad \text{iff} \quad \tau_\Sigma^b[\Phi] \leq \Omega(T); \\ \phi \in T_\Sigma & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T). \end{aligned}$$

Therefore, $\phi \in C_\Sigma(\Phi)$ if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\Phi \subseteq T_\Sigma$ implies $\phi \in T_\Sigma$, if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\tau_\Sigma^b[\Phi] \leq \Omega(T)$ implies $\tau_\Sigma^b[\phi] \leq \Omega(T)$, if and only if, by Proposition 918, $\tau_\Sigma^b[\phi] \leq D^{\mathcal{I}*}(\tau_\Sigma^b[\Phi])$.

For (b), let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. Then we have, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\begin{aligned} \phi \approx \psi \in \Omega_\Sigma(T) & \quad \text{iff} \quad \vec{I}_\Sigma^b[\phi, \psi] \leq T \quad (\text{Corollary 791}) \\ & \quad \text{iff} \quad \tau^b[\vec{I}_\Sigma^b[\phi, \psi]] \leq \Omega(T). \quad (\text{truth equationality}) \end{aligned}$$

Using again Proposition 918, we conclude that

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^b[\vec{I}_\Sigma^b[\phi, \psi]]).$$

Therefore $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via $(\tau^b, \vec{I}^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$. ■

Putting together Theorems 912, 913 and 921, we get the following fundamental result to the effect that syntactic WF algebraizability boils down to the equivalence of a π -institution with its associated equational π -structure via a conjugate pair of transformations.

Theorem 922 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WF algebraizable if and only if it is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}^*}$ of transformations.*

Proof: If $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair of transformations, then, by Theorem 912, it is syntactically protoalgebraic and, by Theorem 913, it is family truth equational. Therefore, by Theorem 915, it is syntactically WF algebraizable.

If, conversely, $\mathcal{I}$ is syntactically WF algebraizable, then, by Theorem 921, it is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair of transformations. ■

We close the section by slightly generalizing the preceding characterization. Namely, we show that existence of an equivalence with an equational π -structure induced by conjugate transformations is sufficient to yield syntactic WF algebraizability.

Theorem 923 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WF algebraizable if and only if it is equivalent to an equational π -structure via a conjugate pair of transformations.*

Proof: If $\mathcal{I}$ is syntactically WF algebraizable, then the conclusion follows from Theorem 922. Conversely, if $\mathcal{I}$ is equivalent to an algebraic π -structure via a conjugate pair of transformations, then it is syntactically protoalgebraic by Theorem 912 and family truth equational by Theorem 913, whence it is syntactically WF algebraizable. ■

Taking into account Theorem 904, we have the following alternative characterization of syntactically WF algebraizable π -institutions.

Theorem 924 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WF algebraizable if and only if there is a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 923 and Theorem 896. The “if” is given by Theorem 904 and Theorem 923. ■

12.5 Syntactic Weak Algebraizability

Syntactic WF algebraizability determines one of the highest levels of the main algebraic hierarchy of π -institutions. Since every syntactically WF algebraizable π -institution is, in particular, family reflective, it follows that

every syntactically WF algebraizable π -institution is systemic. To avoid systematicity, one has to weaken the hypothesis of family reflectivity. In this section, we follow this line of thought by keeping the assumption of syntactic protoalgebraicity, but insisting only that the π -institution is system truth equational, rather than family truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

We say that $\mathcal{I}$ is $R^\mathcal{I}L^\mathcal{I}$ -(**syntactically**) **fortified** if:

- The reflexive core $R^\mathcal{I}$ is Leibniz;
- The left Suszko core $L^\mathcal{I}$ is left adequate.

A π -institution $\mathcal{I}$ is **syntactically weakly algebraizable** (abbreviated to **syntactically W algebraizable**) if:

- $\mathcal{I}$ is $R^\mathcal{I}L^\mathcal{I}$ -fortified;
- $\mathcal{I}$ is protoalgebraic;
- $\mathcal{I}$ is system injective.

By Corollary 300, under protoalgebraicity, the six properties of system injectivity, left injectivity, system reflectivity, left reflectivity, system complete reflectivity and left complete reflectivity coincide. This enables us to formulate the following alternative characterization of syntactic weak algebraizability.

Theorem 925 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly algebraizable if and only if it is syntactically protoalgebraic and system (or, equivalently, left) truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically weakly algebraizable. Then, on the one hand, it is protoalgebraic and has a Leibniz reflexive core. Thus, by Theorem 805, it is syntactically protoalgebraic. On the other, it is, by Theorem 300, left c-reflective and has a left adequate left Suszko core. Therefore, by Theorem ??, it is left truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically protoalgebraic and left truth equational. Then, by Theorem 805, it is protoalgebraic and has a Leibniz reflexive core, and, by Theorem 871, it is left c-reflective and has a left adequate left Suszko core. Therefore, by definition, $\mathcal{I}$ is syntactically weakly algebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic weak algebraizability classes of π -institutions.

Theorem 926 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly algebraizable if and only if $\mathcal{I}$ is weakly algebraizable and $R^\mathcal{I}L^\mathcal{I}$ -fortified.*

Proof: $\mathcal{I}$ is syntactically weakly algebraizable if and only if, by definition, it is $R^\mathcal{I}L^\mathcal{I}$ -fortified, protoalgebraic and system injective, i.e., iff it is, by definition, $R^\mathcal{I}L^\mathcal{I}$ -fortified and weakly algebraizable. ■

Previous results, put together, also allow us to provide an alternative characterization of syntactic weak algebraizability in terms of isomorphisms between complete lattices of theory systems.

Theorem 927 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly algebraizable if and only if it is $R^\mathcal{I}L^\mathcal{I}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiSys}^\mathcal{I}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: We have that $\mathcal{I}$ is syntactically weakly algebraizable if and only if, by Theorem 926, it is $R^\mathcal{I}L^\mathcal{I}$ -fortified and weakly algebraizable, if and only if, by Theorem 298, it is $R^\mathcal{I}L^\mathcal{I}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \text{FiSys}^\mathcal{I}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism. ■

Next, we show that syntactic weak algebraizability may also be characterized by stability in conjunction with the existence of an equivalence between the systemic skeleton of a π -institution and its algebraic π -structure counterpart via a pair of conjugate transformations. To start, we define the *systemic skeleton* of a given π -institution.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall that $\text{ThSys}(\mathcal{I})$ forms a complete lattice $\mathbf{ThSys}(\mathcal{I}) = \langle \text{ThSys}(\mathcal{I}), \leq \rangle$ under signature wise inclusion. Therefore, we are justified in defining the π -structure

$$\mathcal{K}^\mathcal{I} = \langle \mathbf{F}, K^\mathcal{I} \rangle$$

of $\mathcal{I}$ by stipulating that $K^\mathcal{I} : \mathcal{P}\text{SEN} \rightarrow \mathcal{P}\text{SEN}$ is the closure family on $\mathbf{F}$ corresponding to the closed set family $\text{ThSys}(\mathcal{I})$. We call $\mathcal{K}^\mathcal{I}$ the **systemic skeleton** of $\mathcal{I}$.

We give an example to show that, in general, $\mathcal{K}^\mathcal{I}$ is not a π -institution, since $K^\mathcal{I} : \mathcal{P}\text{SEN} \rightarrow \mathcal{P}\text{SEN}$ may not satisfy structurality.

Example 928 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be defined as follows:*

- $\mathbf{Sign}^b$ is the category with objects Σ, Σ' and, except the identities, a morphism $f : \Sigma \rightarrow \Sigma$ and two morphisms $g, h : \Sigma \rightarrow \Sigma'$, satisfying the following composition rules:

$$f \circ f = f, \quad gf = h, \quad hf = h.$$

- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is defined by setting

$$\mathbf{SEN}^b(\Sigma) = \{0, 1, 2\}, \quad \mathbf{SEN}^b(\Sigma') = \{a, b, c\}$$

and

$x \in \mathbf{SEN}^b(\Sigma)$	$\mathbf{SEN}^b(f)(x)$	$\mathbf{SEN}^b(g)(x)$	$\mathbf{SEN}^b(h)(x)$
0	0	a	a
1	0	b	a
2	2	c	c

- Finally, N^b is the trivial category of natural transformations (consisting of the projections only).

Next define the π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by setting

$$\mathcal{C}_\Sigma = \{\{2\}, \{1, 2\}, \{0, 1, 2\}\} \quad \text{and} \quad \mathcal{C}_{\Sigma'} = \{\{b, c\}, \{a, b, c\}\}.$$

This π -institution has six theory families, having the lattice structure shown on the left below. It has, however, only three theory systems, whose lattice structure is given on the right.

The theory systems of $\mathcal{I}$ are the theory families of the systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$. We can see that $\mathcal{K}^{\mathcal{I}}$ is not a π -institution by considering $\Phi = \{1\} \subseteq \text{SEN}^b(\Sigma)$. We have

$$\begin{aligned} \text{SEN}^b(g)(K_{\Sigma}^{\mathcal{I}}(\{1\})) &= \text{SEN}^b(g)(\cap \{T_{\Sigma} : \{\{1\}, \emptyset\} \leq T \in \text{ThSys}(\mathcal{I})\}) \\ &= \text{SEN}^b(g)(\{0, 1, 2\}) \\ &= \{a, b, c\}. \end{aligned}$$

On the other hand,

$$\begin{aligned} K_{\Sigma'}^{\mathcal{I}}(\text{SEN}^b(g)(\{1\})) &= K_{\Sigma'}^{\mathcal{I}}(\{b\}) \\ &= \cap \{T_{\Sigma'} : \{\emptyset, \{b\}\} \leq T \in \text{ThSys}(\mathcal{I})\} \\ &= \{b, c\}. \end{aligned}$$

Therefore

$$\text{SEN}^b(g)(K_{\Sigma}^{\mathcal{I}}(\{1\})) \notin K_{\Sigma'}^{\mathcal{I}}(\text{SEN}^b(g)(\{1\}))$$

showing that $K^{\mathcal{I}}$ is not structural and, hence, $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is a π -structure, but not a π -institution.

We now resume our work on the characterization of syntactic weak algebraizability. We will again make use of the equational π -structure $\mathcal{Q}^{\mathcal{I}^*} = \langle \mathbf{F}^2, D^{\mathcal{I}^*} \rangle$ associated with a protoalgebraic π -institution $\mathcal{I}$. Recall from Section 12.4 that this is the π -structure whose closure operator is the one corresponding to the closure family $\text{ConSys}^{\mathcal{I}^*}(\mathcal{F})$.

Our first result connecting syntactic weak algebraizability of a π -institution with the associated equational π -structure shows that, if a π -institution is syntactically weakly algebraizable, then its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to its associated equational π -structure $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair of transformations.

Theorem 929 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically weakly algebraizable π -institution based on $\mathbf{F}$. Then $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair $(\tau^b, \vec{I}^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}^*}$ of transformations. More precisely:*

- $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, is a set of witnessing transformations of the syntactic protoalgebraicity of $\mathcal{I}$;
- $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$, with a single distinguished argument, is a set of witnessing equations for the left truth equationality of $\mathcal{I}$.

Proof: Suppose that $\mathcal{I}$ is syntactically weakly algebraizable. Then, by Theorem 925, $\mathcal{I}$ is syntactically protoalgebraic and left truth equational. Therefore, there exist a set $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ of natural transformations in N^b , with two distinguished arguments, witnessing the syntactic protoalgebraicity of $\mathcal{I}$, and a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with a single distinguished argument, witnessing left truth equationality. To verify the conclusion, observe, first, that $\tau_\Sigma^b : \text{SEN}^b(\Sigma) \rightarrow \text{SenFam}(\mathbf{F}^2)$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, as the sentence family $\tau_\Sigma^b[\phi]$ and $\vec{I}_\Sigma^b : \text{SEN}^b(\Sigma)^2 \rightarrow \text{SenFam}(\mathbf{F})$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, as the sentence family $\vec{I}_\Sigma^b[\phi, \psi]$ are as required. Therefore, by Proposition 901, it suffices to show that:

(a) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in K_\Sigma^{\mathcal{I}}(\Phi) \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq D^{\mathcal{I}*}(\tau_\Sigma^b[\Phi]);$$

(b) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$D^{\mathcal{I}*}(\phi \approx \psi) = D^{\mathcal{I}*}(\tau^b[\vec{I}_\Sigma^b[\phi, \psi]]).$$

For (a), let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. Note that, for all $T \in \text{ThSys}(\mathcal{I})$, we have

$$\begin{aligned} \Phi \subseteq T_\Sigma & \quad \text{iff} \quad \Phi \subseteq \overleftarrow{T}_\Sigma \quad (T \in \text{ThSys}(\mathcal{I})) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\Phi] \leq \Omega(T) \quad (\text{left truth equationality}) \end{aligned}$$

and, similarly,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Therefore, $\phi \in K_\Sigma^{\mathcal{I}}(\Phi)$ if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\Phi \subseteq T_\Sigma$ implies $\phi \in T_\Sigma$, if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\tau_\Sigma^b[\Phi] \leq \Omega(T)$ implies $\tau_\Sigma^b[\phi] \leq \Omega(T)$, if and only if, by stability, for all $T \in \text{ThFam}(\mathcal{I})$, $\tau_\Sigma^b[\Phi] \leq \Omega(T)$ implies $\tau_\Sigma^b[\phi] \leq \Omega(T)$, if and only if, by Proposition 918, $\tau_\Sigma^b[\phi] \leq D^{\mathcal{I}*}(\tau_\Sigma^b[\Phi])$.

For (b), let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. Then we have, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\begin{aligned} \phi \approx \psi \in \Omega_\Sigma(T) & \quad \text{iff} \quad \vec{I}_\Sigma^b[\phi, \psi] \leq T \quad (\text{Corollary 791}) \\ & \quad \text{iff} \quad \vec{I}_\Sigma^b[\phi, \psi] \leq \overleftarrow{T} \quad (T \in \text{ThSys}(\mathcal{I})) \\ & \quad \text{iff} \quad \tau^b[\vec{I}_\Sigma^b[\phi, \psi]] \leq \Omega(T). \quad (\text{left truth equationality}) \end{aligned}$$

Using again Proposition 918 and stability, we conclude that

$$D^{\mathcal{I}^*}(\phi \approx \psi) = D^{\mathcal{I}^*}(\tau^b[\vec{I}^b_\Sigma[\phi, \psi]]).$$

Therefore $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via $(\tau^b, \vec{I}^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}^*}$. ■

Towards the converse, we show, first, that, if a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is such that there exists an equivalence $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$, via a conjugate pair of transformations, between its systemic skeleton and an equational π -structure $\mathcal{Q}$, then I^b defines Leibniz congruence systems of theory systems of $\mathcal{I}$.

Recall that for a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$, and a set $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ of natural transformations in N^b , with two distinguished arguments, we define, for all $T \in \mathbf{SenFam}(\mathcal{I})$, $\vec{I}^b(T) = \{\vec{I}^b_\Sigma(T)\}_{\Sigma \in |\mathbf{Sign}^b|}$ by setting, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$\vec{I}^b_\Sigma(T) = \{\langle \phi, \psi \rangle \in \mathbf{SEN}^b(\Sigma)^2 : I^b_\Sigma[\phi, \psi] \leq T\}.$$

Proposition 930 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations, then, for all $T \in \mathbf{ThSys}(\mathcal{I})$, $\Omega(T) = \vec{I}^b(T)$.*

Proof: Let $T \in \mathbf{ThSys}(\mathcal{I})$. It suffices to show, by Corollary 98, that $\vec{I}^b(T)$ is a congruence system on $\mathbf{F}$ compatible with T . We know by Lemma 93 that it is a relation system on $\mathbf{F}$.

Suppose $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Since $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ is equational, we have $\phi \approx \phi \in D_\Sigma(\emptyset)$. Therefore, by interpretability, $I^b_\Sigma[\phi, \phi] \leq K^{\mathcal{I}}(\emptyset) = C(\emptyset) \leq T$. Hence, $\langle \phi, \phi \rangle \in \vec{I}^b_\Sigma(T)$ and $\vec{I}^b(T)$ is reflexive.

Suppose, now, that $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$. Since $\mathcal{Q}$ is equational, we have that $\psi \approx \phi \in D_\Sigma(\phi \approx \psi)$. Therefore, by interpretability, $I^b_\Sigma[\psi, \phi] \leq K^{\mathcal{I}}(I^b_\Sigma[\phi, \psi])$. Since $T \in \mathbf{ThSys}(\mathcal{I})$, this implies that, if $I^b_\Sigma[\phi, \psi] \leq T$, then $I^b_\Sigma[\psi, \phi] \leq T$. In other words $\langle \phi, \psi \rangle \in \vec{I}^b_\Sigma(T)$ implies $\langle \psi, \phi \rangle \in \vec{I}^b_\Sigma(T)$. Therefore, $\vec{I}^b(T)$ is also symmetric.

Suppose, next, that $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$. Since $\mathcal{Q}$ is equational, we have that $\phi \approx \chi \in D_\Sigma(\phi \approx \psi, \psi \approx \chi)$. Therefore, by interpretability, $I^b_\Sigma[\phi, \chi] \leq K^{\mathcal{I}}(I^b_\Sigma[\phi, \psi], I^b_\Sigma[\psi, \chi])$. Since $T \in \mathbf{ThSys}(\mathcal{I})$, this implies that, if $I^b_\Sigma[\phi, \psi], I^b_\Sigma[\psi, \chi] \leq T$, then $I^b_\Sigma[\phi, \chi] \leq T$. In other words, $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \vec{I}^b_\Sigma(T)$ imply $\langle \phi, \chi \rangle \in \vec{I}^b_\Sigma(T)$. Therefore, $\vec{I}^b(T)$ is transitive.

We have now shown that $\vec{I}^b(T)$ is an equivalence system on $\mathbf{F}$. It remains to show that it satisfies the congruence property and that it is compatible with T .

Suppose that $\sigma^b \in N^b$, $\Sigma \in |\mathbf{Sign}^b|$ and $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$. Since $\mathcal{Q}$ is equational, we have that $\sigma_\Sigma^b(\vec{\phi}) \approx \sigma_\Sigma^b(\vec{\psi}) \in D_\Sigma(\vec{\phi} \approx \vec{\psi})$ (recall that $\vec{\phi} \approx \vec{\psi}$ means $\{\phi_i \approx \psi_i : i < k\}$). Therefore, by interpretability,

$$I_\Sigma^b[\sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi})] \leq K^\mathcal{I}(\bigcup \{I_\Sigma^b[\phi_i, \psi_i] : i < k\}).$$

Since $T \in \text{ThSys}(\mathcal{I})$, this implies that, if, for all $i < k$, $I_\Sigma^b[\phi_i, \psi_i] \leq T$, then $I_\Sigma^b[\sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi})] \leq T$. In other words $\langle \phi_i, \psi_i \rangle \in \overleftarrow{I}_\Sigma^b(T)$, for all $i < k$, imply $\langle \sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi}) \rangle \in \overleftarrow{I}_\Sigma^b(T)$. Therefore, $\overleftarrow{I}^b(T)$ satisfies the congruence property.

Finally, to see that $\overleftarrow{I}^b(T)$ is compatible with T , suppose that $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. Since $\mathcal{Q}$ is equational and $\tau^b \in N^b$, we have, by Lemma 910,

$$\tau_\Sigma^b[\psi] \leq D(\tau_\Sigma^b[\phi], \phi \approx \psi).$$

By interpretability, this yields

$$I^b[\tau_\Sigma^b[\psi]] \leq K^\mathcal{I}(I^b[\tau_\Sigma^b[\phi]], I_\Sigma^b[\phi, \psi]).$$

Since (τ^b, I^b) is a conjugate pair, the latter is equivalent to

$$\psi \in K^\mathcal{I}(\phi, I_\Sigma^b[\phi, \psi]).$$

In other words, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\phi \in T_\Sigma \quad \text{and} \quad \langle \phi, \psi \rangle \in \overleftarrow{I}_\Sigma^b(T) \quad \text{imply} \quad \psi \in T_\Sigma.$$

Hence $\overleftarrow{I}^b(T)$ is compatible with T . ■

Using Proposition 930, we can show that stability and the existence of an equivalence between the systemic skeleton and an equational π -structure ensure syntactic protoalgebraicity.

Theorem 931 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is stable and its systemic skeleton $\mathcal{K}^\mathcal{I} = \langle \mathbf{F}, K^\mathcal{I} \rangle$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^\mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations I^b .*

Proof: Suppose that $\mathcal{I}$ is stable and its systemic skeleton $\mathcal{K}^\mathcal{I} = \langle \mathbf{F}, K^\mathcal{I} \rangle$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^\mathcal{I} \rightleftarrows \mathcal{Q}$ of transformations. Then, we have, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\begin{aligned} \Omega(T) &= \Omega(\overleftarrow{T}) \quad (\text{by stability}) \\ &= \overleftarrow{I}^b(\overleftarrow{T}) \quad (\text{by Proposition 930}) \\ &= \overleftarrow{I}^b(T). \quad (\text{by Proposition 99}) \end{aligned}$$

Therefore, $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations I^b . $\blacksquare$

Finally, before the main theorem, we show that stability and the existence of a transformational equivalence between the systemic skeleton and an equational π -structure ensure left truth equationality.

Theorem 932 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is left truth equational, with witnessing equations τ^b .*

Proof: We have, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \overleftarrow{T}_{\Sigma} & \text{ iff } I^b[\tau_{\Sigma}^b[\phi]] \leq \overleftarrow{T} & ((\tau^b, I^b) \text{ an equivalence}) \\ & \text{ iff } I^b[\tau_{\Sigma}^b[\phi]] \leq T & (\text{by Proposition 99}) \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \Omega(T). & (\text{by Theorem 931}) \end{aligned}$$

Therefore, $\mathcal{I}$ is left truth equational, with witnessing equations τ^b . $\blacksquare$

Putting together Theorems 931, 932 and 929, we get the following fundamental result to the effect that syntactic weak algebraizability boils down to stability, together with the equivalence of the systemic skeleton of a π -institution with its associated equational π -structure via a conjugate pair of transformations.

Theorem 933 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly algebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}^*}$ of transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair of transformations. Then, by Theorem 931, it is syntactically protoalgebraic and, by Theorem 932, it is left truth equational. Therefore, by Theorem 925, it is syntactically weakly algebraizable.

If, conversely, $\mathcal{I}$ is syntactically weakly algebraizable, then, on the one hand, it is protoalgebraic and, therefore, stable, and, on the other, by Theorem 929, it is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair of transformations. $\blacksquare$

Generalizing again, we show that stability together with the existence of an equivalence of the systemic skeleton with an equational π -structure, induced by conjugate transformations, is sufficient to yield syntactic weak algebraizability.

Theorem 934 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly algebraizable if and only if it is stable and its systemic skeleton is equivalent to an algebraic π -structure via a conjugate pair of transformations.*

Proof: If $\mathcal{I}$ is syntactically weakly algebraizable, then the conclusion follows from Theorem 933. Conversely, if $\mathcal{K}^{\mathcal{I}}$ is equivalent to an algebraic π -structure via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically protoalgebraic by Theorem 931 and left truth equational by Theorem 932, whence it is syntactically weakly algebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically weakly algebraizable π -institutions.

Theorem 935 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly algebraizable if and only if it is stable and there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 934 and Theorem 896. The “if” is given by Theorem 904 and Theorem 934. ■

Let us give, in closing the section, the picture of the **weak algebraizability hierarchy** that we have established, consisting of both semantic and syntactic classes of π -institutions.

We give an example of a syntactically weakly algebraizable π -institution which is not syntactically weakly family algebraizable.

Example 936 **EXAMPLE NOT FOUND YET!!**

12.6 Syntactic WS PreAlgebraizability

Syntactic WS prealgebraizability, requires, like syntactic WF algebraizability, the monotonicity of the Leibniz operator on theory systems and the injectivity of the Leibniz operator on theory systems but, unlike WF algebraizability, it requires these two properties only on theory systems and not on the entire complete lattice of theory families. As a consequence of this weakened requirement, syntactic WS prealgebraizability implies neither systemicity (as does syntactic WF algebraizability) nor the even weaker condition of stability (as do both kinds of syntactic algebraizability). Thus, as other conditions that were under our scrutiny previously, it allows us to consider for membership π -institutions that are not necessarily stable.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

We say that $\mathcal{I}$ is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -(**syntactically**) **fortified** if:

- The reflexive core $R^{\mathcal{I}}$ is Leibniz;
- The system core $Z^{\mathcal{I}}$ is adequate.

$\mathcal{I}$ is **syntactically weakly system prealgebraizable** (abbreviated to **syntactically WS prealgebraizable**) if:

- $\mathcal{I}$ is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is prealgebraic;
- $\mathcal{I}$ is system injective.

By Theorem 248, under prealgebraicity, the properties of system injectivity, system reflectivity and system complete reflectivity coincide. As a result, we have the following alternative characterization of syntactic weak system prealgebraizability.

Theorem 937 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if it is syntactically prealgebraic and system truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically weakly system prealgebraizable. Then, on the one hand, it is prealgebraic and has a Leibniz reflexive core. Thus, by Theorem 788, it is syntactically prealgebraic. On the other, it is, by Theorem 248, system c-reflective and has an adequate system core. Therefore, by Theorem 889, it is system truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically prealgebraic and system truth equational. Then, by Theorem 788, it is prealgebraic and has a Leibniz reflexive core, and, by Theorem 889, it is system c-reflective and has an

adequate system core. Therefore, by definition, $\mathcal{I}$ is syntactically weakly system prealgebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic weak system prealgebraizability classes of π -institutions.

Theorem 938 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if $\mathcal{I}$ is weakly system prealgebraizable and $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified.*

Proof: $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if, by definition, it is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified, prealgebraic and system injective, i.e., iff it is, by definition, $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and weakly system prealgebraizable. ■

Previous results, put together, also allow us to provide an alternative characterization of syntactic weak system prealgebraizability in terms of morphisms between complete lattices of theory systems.

Theorem 939 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if it is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding.

Proof: We have that $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if, by Theorem 938, it is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and weakly system prealgebraizable, if and only if, by Theorem 256, it is $R^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding ■

Next, we show that syntactic weak system prealgebraizability may also be characterized by the existence of an equivalence between the systemic skeleton of a π -institution and an algebraic π -structure associated with the π -institution (different, in general, than $\mathcal{Q}^{\mathcal{I}*}$) via a pair of conjugate transformations.

We embark on the path by defining first the algebraic π -structure $\mathcal{Q}^{\mathcal{I}\bullet}$ associated with a given π -institution $\mathcal{I}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall the definition of the class $\text{AlgSys}^{\bullet}(\mathcal{I})$ of all $\mathbf{F}$ -algebraic systems reduced with respect to $\mathcal{I}$ -filter systems,

$$\text{AlgSys}^{\bullet}(\mathcal{I}) = \{ \mathcal{A} : (\exists T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})) (\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}) \}.$$

Given an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, we define the class of $\mathcal{I}$ -congruence systems on $\mathcal{A}$ by

$$\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A}) = \{\theta \in \text{ConSys}(\mathbf{A}) : \mathcal{A}/\theta \in \text{AlgSys}^\bullet(\mathcal{I})\}.$$

It turns out that congruence systems in $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ have a straightforward characterization.

Proposition 940 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A}) = \{\theta \in \text{ConSys}(\mathbf{A}) : (\exists T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A}))(\Omega^{\mathcal{A}}(T) = \theta)\}.$$

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system.

Suppose, first, that $\theta \in \text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$. By definition, $\mathcal{A}/\theta \in \text{AlgSys}^\bullet(\mathcal{I})$. Thus, there exists $T' \in \text{FiSys}^{\mathcal{I}}(\mathcal{A}/\theta)$, such that

$$\Omega^{\mathcal{A}/\theta}(T') = \Delta^{\mathcal{A}/\theta}.$$

By applying the inverse of the quotient morphism $\langle I, \pi^\theta \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$, we get

$$(\pi^\theta)^{-1}(\Omega^{\mathcal{A}/\theta}(T')) = (\pi^\theta)^{-1}(\Delta^{\mathcal{A}/\theta}).$$

Since $\langle I, \pi^\theta \rangle$ is surjective, we get by Proposition 24 and Corollary 55, that $(\pi^\theta)^{-1}(T') \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$ and

$$\Omega^{\mathcal{A}}((\pi^\theta)^{-1}(T')) = \theta.$$

Therefore, there exists $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \theta$.

Suppose, conversely, that $\theta \in \text{ConSys}(\mathbf{A})$, with $\Omega^{\mathcal{A}}(T) = \theta$, for some $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$. Then, we have $\Omega^{\mathcal{A}/\theta}(T/\theta) = \Delta^{\mathcal{A}/\theta}$ and, therefore, by definition, $\mathcal{A}/\theta \in \text{AlgSys}^\bullet(\mathcal{I})$, implying that $\theta \in \text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$. ■

In general, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ and an $\mathbf{F}$ -algebraic system $\mathcal{A}$, the family $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ of systemic $\mathcal{I}$ -congruence systems on $\mathcal{A}$ need not be closed under signature-wise intersections, i.e., may not form a closure family on $\mathbf{A}^2$. However, we can show that, if $\mathcal{I}$ is prealgebraic, this is always the case.

Proposition 941 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a prealgebraic π -institution based on $\mathbf{F}$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ is closed under arbitrary intersections and, therefore, forms a closure family on $\mathbf{A}^2$.*

Proof: First, note that $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ has a top element $\nabla^{\mathcal{A}}$. To see this, observe that $\mathcal{A}/\nabla^{\mathcal{A}}$ is a trivial algebraic system, which is always a member of $\text{AlgSys}^\bullet(\mathcal{I})$.

It suffices now to show that $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$ is closed under arbitrary intersections. To this end, suppose $\theta^i \in \text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$, for $i \in I$. By Proposition 940, for all $i \in I$, there exists $T^i \in \text{FiSys}^{\mathcal{I}}(\mathcal{A}/\theta^i)$, such that $\Omega^{\mathcal{A}}(T^i) = \theta^i$. But, by Lemma 23 and prealgebraicity, we get that

$$\Omega^{\mathcal{A}}\left(\bigcap_{i \in I} T^i\right) = \bigcap_{i \in I} \Omega^{\mathcal{A}}(T^i) = \bigcap_{i \in I} \theta^i.$$

Now, again by Proposition 940, we conclude that $\bigcap_{i \in I} \theta^i \in \text{ConSys}^{\mathcal{I}\bullet}(\mathcal{A})$. ■

Applying Proposition 941 to the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \rightarrow \mathbf{F}$ is the identity morphism, we get the following

Corollary 942 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a prealgebraic π -institution based on $\mathbf{F}$. Then, $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{F})$ is closed under arbitrary intersections and, therefore, forms a closure family on $\mathbf{F}^2$.*

Proof: This is a special case of Proposition 941. ■

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a prealgebraic π -institution. We define, in accordance with Corollary 942, the **systemic equational π -structure $\mathcal{Q}^{\mathcal{I}\bullet}$ associated with $\mathcal{I}$** to be the π -structure $\mathcal{Q}^{\mathcal{I}\bullet} = \langle \mathbf{F}^2, D^{\mathcal{I}\bullet} \rangle$, where $D^{\mathcal{I}\bullet}$ is the closure (operator) family corresponding to the closure family $\text{ConSys}^{\mathcal{I}\bullet}(\mathcal{F})$.

We recall, also, the definition of the systemic skeleton of $\mathcal{I}$, i.e., of the π -structure

$$\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle,$$

where $K^{\mathcal{I}} : \mathcal{P}\text{SEN} \rightarrow \mathcal{P}\text{SEN}$ is the closure operator on $\mathbf{F}$ corresponding to the closure family $\text{ThSys}(\mathcal{I})$.

Now we have the components needed to resume work on the characterization of syntactic weak system prealgebraizability. Our first result connecting syntactic weak system prealgebraizability of a π -institution with the associated systemic equational π -structure shows that, if a π -institution is syntactically weakly system prealgebraizable, then its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to its associated systemic equational π -structure $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of transformations.

Theorem 943 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically weakly system prealgebraizable π -institution based on $\mathbf{F}$. Then $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^b, \vec{I}^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations. More precisely:*

- $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with two distinguished arguments, is a set of witnessing transformations of the syntactic prealgebraicity of $\mathcal{I}$;

- $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$, with a single distinguished argument, is a set of witnessing equations for the system truth equationality of $\mathcal{I}$.

Proof: Suppose that $\mathcal{I}$ is syntactically weakly system prealgebraizable. Then, by Theorem 937, $\mathcal{I}$ is syntactically prealgebraic and system truth equational. Therefore, there exist a set $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ of natural transformations in N^b , with two distinguished arguments, witnessing the syntactic prealgebraicity of $\mathcal{I}$, and a set $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ of natural transformations in N^b , with a single distinguished argument, witnessing system truth equationality. To verify the conclusion, observe, first, that $\tau_\Sigma^b : \text{SEN}^b(\Sigma) \rightarrow \text{SenFam}(\mathbf{F}^2)$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, as the sentence family $\tau_\Sigma^b[\phi]$, and $\vec{I}_\Sigma^b : \text{SEN}^b(\Sigma)^2 \rightarrow \text{SenFam}(\mathbf{F})$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, as the sentence family $\vec{I}_\Sigma^b[\phi, \psi]$, are as required. Therefore, by Proposition 901, it suffices to show that:

- (a) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in K_\Sigma^{\mathcal{I}}(\Phi) \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq D^{\mathcal{I}\bullet}(\tau_\Sigma^b[\Phi]);$$

- (b) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$D^{\mathcal{I}\bullet}(\phi \approx \psi) = D^{\mathcal{I}\bullet}(\tau^b[\vec{I}_\Sigma^b[\phi, \psi]]).$$

For (a), let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. Note that, for all $T \in \text{ThSys}(\mathcal{I})$, we have, by system truth equationality,

$$\begin{aligned} \Phi \subseteq T_\Sigma & \quad \text{iff} \quad \tau_\Sigma^b[\Phi] \leq \Omega(T) \\ \phi \in T_\Sigma & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T). \end{aligned}$$

Therefore, $\phi \in K_\Sigma^{\mathcal{I}}(\Phi)$ if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\Phi \subseteq T_\Sigma$ implies $\phi \in T_\Sigma$, if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\tau_\Sigma^b[\Phi] \leq \Omega(T)$ implies $\tau_\Sigma^b[\phi] \leq \Omega(T)$, if and only if, by Proposition 940, $\tau_\Sigma^b[\phi] \leq D^{\mathcal{I}\bullet}(\tau_\Sigma^b[\Phi])$.

For (b), let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. Then we have, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\begin{aligned} \phi \approx \psi \in \Omega_\Sigma(T) & \quad \text{iff} \quad \vec{I}_\Sigma^b[\phi, \psi] \leq T \quad (\text{Corollary 770}) \\ & \quad \text{iff} \quad \tau^b[\vec{I}_\Sigma^b[\phi, \psi]] \leq \Omega(T). \\ & \quad (\text{system truth equationality}) \end{aligned}$$

Using again Proposition 940, we conclude that

$$D^{\mathcal{I}\bullet}(\phi \approx \psi) = D^{\mathcal{I}\bullet}(\tau^b[\vec{I}_\Sigma^b[\phi, \psi]]).$$

Therefore $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via $(\tau^b, \vec{I}^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$. ■

We show, next that the existence of an equivalence between the systemic skeleton of a given π -institution and an equational π -structure ensures syntactic prealgebraicity.

Theorem 944 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If the systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ of $\mathcal{I}$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b .*

Proof: Suppose that $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations. Then, we have, by Proposition 930, that, for all $T \in \text{ThSys}(\mathcal{I})$, $\Omega(T) = \overleftarrow{I^b}(T)$. Therefore, $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations I^b . ■

Finally, as a last step before the main theorem, we show that the existence of a transformational equivalence between the systemic skeleton of a given π -institution and an equational π -structure ensures system truth equationality.

Theorem 945 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If the systemic skeleton $\mathcal{K}^{\mathcal{I}} = \langle \mathbf{F}, K^{\mathcal{I}} \rangle$ of $\mathcal{I}$ is equivalent to an equational π -structure $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}$ of transformations, then $\mathcal{I}$ is system truth equational, with witnessing equations τ^b .*

Proof: We have, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in T_{\Sigma} & \text{ iff } I^b[\tau_{\Sigma}^b[\phi]] \leq T \quad ((\tau^b, I^b) \text{ an equivalence}) \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \Omega(T). \quad (\text{by Theorem 944}) \end{aligned}$$

Therefore, $\mathcal{I}$ is system truth equational, with witnessing equations τ^b . ■

Putting together Theorems 944, 945 and 943, we get the following fundamental result to the effect that syntactic weak system prealgebraizability boils down to the existence of an equivalence of the systemic skeleton of a π -institution with its associated systemic equational π -structure via a conjugate pair of transformations.

Theorem 946 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}^\bullet}$ of transformations.*

Proof: Suppose, first, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair of transformations. Then, by Theorem 944, it is syntactically prealgebraic and, by Theorem 945, it is system truth equational. Therefore, by Theorem 937, it is syntactically weakly system prealgebraizable. If, conversely, $\mathcal{I}$ is syntactically weakly system prealgebraizable, then, by Theorem 943, it is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair of transformations. ■

It turns out that the existence of an equivalence of the systemic skeleton with an equational π -structure, induced by conjugate transformations, is sufficient to yield syntactic weak system prealgebraizability.

Theorem 947 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of transformations.*

Proof: If $\mathcal{I}$ is syntactically weakly system prealgebraizable, then the conclusion follows from Theorem 946. Conversely, if $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically prealgebraic by Theorem 944 and system truth equational by Theorem 945, whence it is syntactically weakly system prealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically weakly system prealgebraizable π -institutions.

Theorem 948 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically weakly system prealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 947 and Theorem 896. The “if” is given by Theorem 904 and Theorem 947. ■

12.7 Syntactic WLC PreAlgebraizability

Between syntactic WS prealgebraizability and syntactic weak algebraizability we find the class of syntactic weakly left c-reflective prealgebraizability. This strengthens WS prealgebraizability by replacing system c-reflectivity by the stronger condition of left c-reflectivity. Alternatively, it weakens syntactic weak algebraizability by replacing ptoalgebraicity by prealgebraicity.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is **syntactically weakly left c-reflectively prealgebraizable** (abbreviated to **syntactically WLC prealgebraizable**) if:

- $\mathcal{I}$ is $R^{\mathcal{I}}L^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is prealgebraic;
- $\mathcal{I}$ is left c-reflective.

We have the following alternative characterization of syntactic WLC prealgebraizability.

Theorem 949 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is syntactically prealgebraic and left truth equational.*

Proof: Assume that $\mathcal{I}$ is syntactically WLC prealgebraizable. Then, on the one hand, it is prealgebraic and has a Leibniz reflexive core. Thus, by Theorem 788, it is syntactically prealgebraic. On the other, it is left c-reflective and has a left adequate left Suszko core. Therefore, by Theorem 871, it is left truth equational.

Assume, conversely, that $\mathcal{I}$ is syntactically prealgebraic and left truth equational. Then, by Theorem 788, it is prealgebraic and has a Leibniz reflexive core, and, by Theorem 871, it is left c-reflective and has a left adequate left Suszko core. Therefore, by definition, $\mathcal{I}$ is syntactically WLC prealgebraizable. ■

Directly from the definitions, we may derive the following relationship between the semantic and syntactic WLC prealgebraizability classes of π -institutions.

Theorem 950 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if $\mathcal{I}$ is WLC prealgebraizable and $R^\mathcal{I}L^\mathcal{I}$ -fortified.*

Proof: $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if, by definition, it is $R^\mathcal{I}L^\mathcal{I}$ -fortified, prealgebraic and left c-reflective, i.e., iff it is, by definition, $R^\mathcal{I}L^\mathcal{I}$ -fortified and WLC prealgebraizable. ■

For an alternative characterization of syntactic WLC prealgebraizability, we take advantage of the corresponding characterization of WLC prealgebraizability in terms of morphisms between complete lattices of theory systems.

Theorem 951 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is $R^\mathcal{I}L^\mathcal{I}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^\mathcal{A} : \mathbf{FiFam}^\mathcal{I}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

$$\Omega^\mathcal{A} : \mathbf{FiSys}^\mathcal{I}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: We have that $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if, by Theorem 950, it is $R^\mathcal{I}L^\mathcal{I}$ -fortified and WLC prealgebraizable, if and only if, by Theorem 276, it is $R^\mathcal{I}L^\mathcal{I}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,

$$\Omega^\mathcal{A} : \mathbf{FiFam}^\mathcal{I}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding $\Omega^\mathcal{A} : \mathbf{FiSys}^\mathcal{I}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$. ■

Recall that syntactic weak system prealgebraizability was characterized by the existence of an equivalence between the systemic skeleton $K^{\mathcal{I}}$ of a π -institution $\mathcal{I}$ and the systemic equational π -structure $Q^{\mathcal{I}^\bullet}$ associated with the π -institution, via a pair of conjugate transformations. To adapt this characterization to capture syntactic WLC prealgebraizability, we need to postulate alongside this equivalence the property of left truth equationality of the π -institution.

Theorem 952 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is left truth equational and its systemic skeleton $K^{\mathcal{I}}$ is equivalent to $Q^{\mathcal{I}^\bullet}$ via a conjugate pair $(\tau^b, I^b) : K^{\mathcal{I}} \rightleftarrows Q^{\mathcal{I}^\bullet}$ of transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is left truth equational and $K^{\mathcal{I}}$ is equivalent to $Q^{\mathcal{I}^\bullet}$ via a conjugate pair of transformations. Then, $\mathcal{I}$ is left truth equational and, by Theorem 944, it is syntactically prealgebraic. Therefore, by Theorem 949, it is syntactically WLC prealgebraizable. If, conversely, $\mathcal{I}$ is syntactically WLC prealgebraizable, then, by Theorem 949, it is left truth equational and it is weakly system prealgebraizable. Thus, by Theorem 943, it is equivalent to $Q^{\mathcal{I}^\bullet}$ via a conjugate pair of transformations. ■

Because of Theorem 947, left truth equationality and the existence of an equivalence of the systemic skeleton with an equational π -structure, induced by conjugate transformations, is sufficient to yield syntactic WLC prealgebraizability.

Theorem 953 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of transformations.*

Proof: If $\mathcal{I}$ is syntactically WLC prealgebraizable, then the conclusion follows from Theorem 952. Conversely, if $K^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair of transformations, then $\mathcal{I}$ is syntactically prealgebraic by Theorem 944. Since, by hypothesis, it is also left truth equational, it is syntactically WLC prealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically WLC prealgebraizable π -institutions.

Theorem 954 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically WLC prealgebraizable if and only if it is left truth equational and there exists a transformational order isomorphism $h : \mathbf{ThFam}(K^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 953 and Theorem 896. The “if” is given by Theorem 904 and Theorem 953. ■

Let us give, in closing the section, the picture of the **weak prealgebraizability hierarchy** that we have established, consisting of both semantic and syntactic classes of π -institutions.

To separate syntactic WLC prealgebraizability from the class lying immediately above it in the hierarchy, we give an example of a syntactically weakly left c-reflective prealgebraizable π -institution which is not syntactically weakly algebraizable.

Example 955 EXAMPLE NOT FOUND YET!!

We also give an example separating syntactic WLC prealgebraizability from the class lying immediately below it in the hierarchy. That is, we present a syntactically weakly system prealgebraizable π -institution which is not syntactically weakly left c-reflective prealgebraizable.

Example 956 EXAMPLE NOT FOUND YET!!

Chapter 13

The Syntactic Leibniz Hierarchy: Parameterlessness

13.1 Introduction

Chapter 13 deals with those classes in the syntactic hierarchy which may be defined using parameter free collections of natural transformations. They include both classes towards the bottom of the hierarchy, such as, e.g., syntactically preequivalential and syntactically equivalential π -institutions, and classes towards the top that include syntactically prealgebraizable and syntactically algebraizable π -institutions. The breadth of classes encompassed in this way is one of the reasons why this chapter is rather long. The role of parameters and parameterlessness was initially understood in the sentential logic framework with the works of Czelakowski on equivalential logics [24, 25], of Blok and Pigozzi on protoalgebraic logics [29] and later in the context of deduction theorems [27, 30, 33] (see, also, the monograph [65]).

In Section 13.2, we introduce the *binary reflexive core* $B^{\mathcal{I}}$ of a π -institution $\mathcal{I}$. This is a version of the reflexive core, used to characterize syntactic prealgebraicity and syntactic protoalgebraicity in Sections 11.2 and 11.3, respectively, but without parameters. Since, as it turns out, $B^{\mathcal{I}}$ coincides with the collection $\ddot{R}^{\mathcal{I}}$ obtained from $R^{\mathcal{I}}$ by substituting for the parameters arbitrary parameter free natural transformations, we drop the notation $B^{\mathcal{I}}$ and denote the binary reflexive core by $\ddot{R}^{\mathcal{I}}$ throughout.

In Section 13.3, we study *syntactic preequivalentiality*, a syntactic property corresponding to equivalentiality, studied in Chapter 5. We say that a π -institution $\mathcal{I}$ is *syntactically preequivalential* if there exists a parameter free collection I^b of natural transformations in N^b , such that I^b has reflexivity, global system transitivity, global system compatibility and the global system modus ponens in $\mathcal{I}$. In that case, I^b is called a set of *witnessing transformations*. Parameter freeness implies that syntactic preequivalentiality is inherited by π -subinstitutions of a syntactically preequivalential π -institution. Moreover, as syntactic preequivalentiality is a form of parameterless syntactic prealgebraicity, the set $\vec{I}^b$ defines Leibniz congruence systems of theory systems, without parameters. Furthermore, syntactic preequivalentiality transfers from a π -institution to all generalized matrix families of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.

Syntactic preequivalentiality implies (semantic) preequivalentiality. Any set of witnessing transformations is included in the binary reflexive core $\ddot{R}^{\mathcal{I}}$ of $\mathcal{I}$, which, provided that $\mathcal{I}$ is syntactically preequivalential, has the system modus ponens in $\mathcal{I}$. It also possesses another important property called *extensionality*. This means that, for every theory system T , $\overleftarrow{\ddot{R}^{\mathcal{I}}}(T) = \overleftarrow{R^{\mathcal{I}}}(T)$. Since, as $\ddot{R}^{\mathcal{I}} \subseteq R^{\mathcal{I}}$, the inclusion $\overleftarrow{\ddot{R}^{\mathcal{I}}}(T) \leq \overleftarrow{R^{\mathcal{I}}}(T)$ holds universally. Thus, extensionality asserts that $\overleftarrow{\ddot{R}^{\mathcal{I}}}(T) \leq \overleftarrow{R^{\mathcal{I}}}(T)$. It turns out that the binary reflexive core having the system modus ponens and extensionality characterize syntactic preequivalentiality. Another characterization asserts its equivalence

with the definability of Leibniz congruence systems of theory systems by the binary reflexive core.

The last part of Section 13.3 delineates the boundary between syntactic equivalentiality and equivalentiality. For this a variant of the Leibniz property of the reflexive core is needed. More precisely, we say that $\ddot{R}^{\mathcal{I}}$ is *locally Leibniz* if, for every signature Σ and all Σ -sentences ϕ, ψ ,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\langle \phi, \psi \rangle}(C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

It is shown that $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional, then $\ddot{R}^{\mathcal{I}}$ is locally Leibniz. Conversely, if $\mathcal{I}$ is preequivalential, then, if $\ddot{R}^{\mathcal{I}}$ is locally Leibniz, then it has the system modus ponens and is extensional. These implications help us characterize syntactically preequivalential π -institutions as those that are preequivalential and have a locally Leibniz binary reflexive core.

In Section 13.4, we study *syntactic equivalentiality*. It results from syntactic preequivalentiality by replacing the system versions of the defining properties by the corresponding global family versions. Otherwise, the development mirrors that of Section 13.3. Syntactic equivalentiality implies both syntactic preequivalentiality and (semantic) equivalentiality. In the first characterization theorem, it is shown that a π -institution $\mathcal{I}$ is syntactically equivalential if and only if its binary reflexive core $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional. Another characterization asserts that $\mathcal{I}$ is syntactically equivalential if and only if its binary reflexive core defines Leibniz congruence systems of theory families in $\mathcal{I}$. Finally, it is shown that the condition that separates syntactic equivalentiality from equivalentiality is the local Leibniz property of the binary reflexive core of $\mathcal{I}$.

In Section 13.5, we study *strong (family) truth equationality*, a version of (family) truth equationality in which the witnessing equations are parameter free. To provide a characterization, analogous to the one given in Section 11.8 for truth equationality, we use the unary Suszko core $\dot{S}^{\mathcal{I}}$ of a π -institution $\mathcal{I}$, also a version of the Suszko core $S^{\mathcal{I}}$ without parameters. The unary Suszko core satisfies the property that, for every theory family T of $\mathcal{I}$, $T \leq \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T))$. If the reverse inclusion also holds for every theory family, then we say that $\dot{S}^{\mathcal{I}}$ is *soluble*. In fact, the solubility property of the unary Suszko core of a π -institution characterizes strong truth equationality. Another characterization states that $\mathcal{I}$ is strongly truth equational if and only if $\dot{S}^{\mathcal{I}}$ defines theory families via their Leibniz congruence systems. Another property that relates the unary Suszko core with both the Leibniz and the Suszko congruence systems is that, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

If, for all signatures Σ and all Σ -sentences ϕ , the reverse inclusion also holds, then $\dot{S}^{\mathcal{I}}$ is said to be *adequate*. Solubility of $\dot{S}^{\mathcal{I}}$ always implies its adequacy.

In general, this is a strict implication. However, provided that $\mathcal{I}$ is family completely reflective, then adequacy of $\dot{S}^{\mathcal{I}}$ implies its solubility. In fact, we get that $\mathcal{I}$ is strongly truth equational if and only if it is family completely reflective and $\dot{S}^{\mathcal{I}}$ is adequate. Thus, adequacy of $\dot{S}^{\mathcal{I}}$ is the property that separates strong truth equationality from family c-reflectivity.

In Section 13.6, we study *strong left truth equationality*, a property that has the same relation to left truth equationality as strong (family) truth equationality, studied in Section 13.5, has to (family) truth equationality. A π -institution is *strongly left truth equational* if it satisfies a condition similar to that defining left truth equationality, but with witnessing equations without parameters. Strong truth equationality is strong enough to imply systemcity and, as a consequence, it implies strong left truth equationality. Given a π -institution $\mathcal{I}$, we introduce the *unary left Suszko core* $\dot{L}^{\mathcal{I}}$ of $\mathcal{I}$, analogous to the left Suszko core $L^{\mathcal{I}}$, but without parameters. It is always the case that, for every theory family T , $\overleftarrow{T} \leq \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T))$. *Left solubility* is the property that holds, by definition, if the reverse inclusion is also valid. We prove that $\mathcal{I}$ is strongly left truth equational if and only if the unary left Suszko core of $\mathcal{I}$ is left soluble. A second characterization asserts that $\mathcal{I}$ is strongly left truth equational if and only if the unary left Suszko core defines theory families in $\mathcal{I}$ “up to arrow”, meaning that, for every theory family T of $\mathcal{I}$, $\overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T)) = \overleftarrow{T}$. To relate strong left truth equationality with its weaker semantic analog, left complete reflectivity, we introduce an analog of the adequacy property for the unary left Suszko core. This simulates the left adequacy property, introduced in Section 11.9, in relation to the left Suszko core $L^{\mathcal{I}}$. In general, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : \dot{L}^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

If the reverse inclusion is also valid, we say that the unary left Suszko core $\dot{L}^{\mathcal{I}}$ is *left adequate*. Again, in general, the solubility of the unary left Suszko core implies its left adequacy. The reverse implication holds provided that $\mathcal{I}$ is left completely reflective. In fact, as it turns out, $\mathcal{I}$ is strongly left truth equational if and only if it is left c-reflective and has a left adequate unary left Suszko core. That is, left adequacy of the left Suszko core is the property dividing strong left truth equationality from left complete reflectivity.

In Section 13.7, we study a third version of strong truth equationality, *strong system truth equationality*. As the name suggests, it is defined by the same condition as strong (family) truth equationality, but restricted to theory systems. Recall that in order to characterize system truth equationality in Section 11.10, we introduced the “systemic” Tarski congruence system of a theory system T in a π -institution $\mathcal{I}$,

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}(\mathcal{I}) \}.$$

Based on this concept, the *unary system core* $\dot{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is defined in a similar way as the system core, but without allowing parameters. In general, it holds that, for every theory system T of $\mathcal{I}$, $T \leq \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T))$. If the reverse inclusion is valid, we say that the unary system core is *soluble*. Solubility of the unary system core $\dot{Z}^{\mathcal{I}}$ of $\mathcal{I}$ intrinsically characterizes strong system truth equationality of $\mathcal{I}$. A second characterization asserts that $\mathcal{I}$ is strongly system truth equational if and only if $\dot{Z}^{\mathcal{I}}$ defines theory systems in terms of Leibniz congruence systems in $\mathcal{I}$.

Strong system truth equationality implies system complete reflectivity, which is its semantic counterpart. The second part of Section 13.7 seeks to pinpoint a property that characterizes strong system truth equationality inside system c-reflectivity. As was the case with strong (family) truth equationality and strong left truth equationality, this property turns out to be the adequacy of the unary system core. In general, for all signatures Σ and all Σ -sentences ϕ , $\dot{Z}^{\mathcal{I}}$ satisfies

$$\bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})).$$

If the reverse inclusion happens to be valid, then we say that $\dot{Z}^{\mathcal{I}}$ is *adequate*. Solubility of $\dot{Z}^{\mathcal{I}}$ implies its adequacy. A sufficient condition for the converse implication to hold is that $\mathcal{I}$ be system c-reflective. In fact, it is shown that a π -institution $\mathcal{I}$ is strongly system truth equational if and only if it is system c-reflective and has an adequate unary system core. Thus, in a certain sense, adequacy of the unary system core is the exact property characterizing the class of strongly system truth equational π -institutions as a subclass of the class of system c-reflective π -institutions.

In Chapter 5, we defined the (semantic) prealgebraizability hierarchy, which involved system monotonicity (prealgebraicity), a certain kind of extensionality and a certain type of injectivity, reflectivity or c-reflectivity. In Section 13.8, we delve into the study of syntactic analogs of classes in this hierarchy. The syntactic analogs entail definability, in some way, of Leibniz congruence systems and of truth. If the former is via parameter free collections of natural transformations, we obtain *syntactic prealgebraizability* classes. On the other hand, if the latter involves parameter free collections of witnessing equations, we talk about *syntactic antiprealgebraizability*.

We say that a π -institution $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified if it has a locally Leibniz binary reflexive core $\ddot{R}^{\mathcal{I}}$ and a left adequate unary left Suszko core $\dot{L}^{\mathcal{I}}$. Then $\mathcal{I}$ is *syntactically strongly left prealgebraizable* if it is preequivalential, left c-reflective and $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified. Building on previous work on syntactic preequivalentiality and strong left truth equationality, it is shown that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is syntactically preequivalential and strongly left truth equational. As concerns its relation with its semantic counterpart, LC prealgebraizability, studied in Section 5.5, it is shown that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and

only if it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified. A third characterization assumes the form of a transfer theorem. It asserts that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and left c-reflective. A fourth characterization uses mappings between lattices of theory families and of congruence systems. According to it, $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left completely order reflecting surjection which restricts to an order embedding $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ that commutes with inverse logical extensions. Yet another characterization involves equivalences between π -structures and equational π -structures associated, in some way, with the π -institution $\mathcal{I}$. We obtain that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\bullet}$ via a conjugate pair (τ^b, I^b) of natural transformations. More generally, the same characterization holds, as long as some equivalence exists between $\mathcal{K}^{\mathcal{I}}$ and an equational π -structure via a conjugate pair of natural transformations. This characterization yields also that syntactic strong left prealgebraizability is characterized by strong left truth equationality and the existence of an order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$ induced by a conjugate pair of natural transformations, where $\mathcal{Q}$ is an equational π -structure.

In the second part of Section 13.8, two weaker properties of π -institutions than syntactic strong left prealgebraizability are introduced. One is obtained by dropping the requirement that the transformations witnessing syntactic prealgebraizability be parameter free and the other by doing the same on the left truth equationality side. These give the notions of *syntactically left prealgebraizable* and *syntactically left antiprealgebraizable* π -institutions, which constitute both superclasses of the syntactically strongly left prealgebraizable ones. After introducing those classes, several characterizations, similar to the ones described above for syntactically strongly left prealgebraizable π -institutions, are provided for each of these two classes.

In Section 13.9, we study versions of syntactic system prealgebraizability, lying below syntactic left prealgebraizability, studied in Section 13.8. As in Section 13.8, we introduce, first, the strongest version which requires both the collection of witnessing transformations and the collection of witnessing equations to be parameter free. A π -institution $\mathcal{I}$ is said to be $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified if it has a locally Leibniz binary reflexive core $\ddot{R}^{\mathcal{I}}$ and an adequate unary system core $\dot{Z}^{\mathcal{I}}$. $\mathcal{I}$ is *syntactically strongly system prealgebraizable* if it is preequivalential (i.e., prealgebraic and system extensional), system c-reflective and $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. In terms of lower classes in the syntactic hierarchy, we get that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is syntactically preequivalential and strongly system truth equational. In relation to the corresponding semantic class, $\mathcal{I}$ is syntactically strongly sys-

tem prealgebraizable if and only if it is system prealgebraizable and $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. In terms of transference of the constituent properties, $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is monotone on theory systems, system extensional and system c-reflective. As far as using mappings between lattices of theory families and of congruence systems, we get that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order embedding which commutes with inverse logical extensions. In terms of equivalences with an equational π -structure, $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair of natural transformations. This yields, additionally, that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThSys}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$ induced by a conjugate pair of natural transformations, where $\mathcal{Q}$ is an equational π -structure.

As was the case in Section 13.8, here, also, below syntactic strong system prealgebraizability we have two properties that result from it by weakening the requirement of parameterlessness either on the side of syntactic preequivalentiality or on the side of strong system truth equationality. In the first instance, we obtain *syntactic system prealgebraizability* and, in the second, *syntactic system antiprealgebraizability*. For these two classes we obtain characterizations paralleling those given for syntactic strong system prealgebraizability in the preceding paragraph. More concretely, we get characterizations in term of constituent properties in the syntactic hierarchy, corresponding properties in the semantic hierarchy, a kind of transfer theorem of constituent properties, in terms of mappings between filter systems and congruence systems, in terms of transformational equivalences with an equational π -structure and, finally, in terms of mappings between theory systems and theory families of equational π -structures.

In Section 13.10, we switch from syntactic prealgebraizability properties, which involve prealgebraicity (system monotonicity), to syntactic algebraizability properties, involving protoalgebraicity (family monotonicity). There are a total of six classes, here, forming an echelon formation of two tiers, the ones at the top involving family c-reflectivity, whereas those at the bottom demanding only system c-reflectivity. In Section 13.10, the properties of the top tier are studied. The three remaining syntactic algebraizability classes are studied in Section 13.11.

A π -institution $\mathcal{I}$ is said to be $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified if it has a locally Leibniz binary reflexive core and an adequate unary Suszko core. It is *syntactically strongly family algebraizable* if it is equivalent (i.e., protoalgebraic and family extensional), family c-reflective and $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified. In terms of syntactic classes, we obtain that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is syntactically equivalential and strongly (family) truth

equational. On the other hand, in terms of semantic classes, we get that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is strongly family algebraizable and $\check{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified. With respect to transference of constituent properties, we get that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is $\check{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is monotone and injective on $\mathcal{I}$ -filter families and family extensional. As far as mappings between posets of theory families and of congruence systems go, $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is $\check{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions. Additionally, looking at equivalences with equational π -structures, we get that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is equivalent to an equational π -structure via a conjugate pair of natural transformations. This characterization yields, also, that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair of natural transformations, where $\mathcal{Q}$ is an equational π -structure.

In the second part of Section 13.10, as was the case with Sections 13.8 and 13.9, we study the two classes obtained by relaxing the parameterlessness requirement on one of the two sides (equivalentiality or strong truth equationality) in the definition of syntactic strong family algebraizability. First, we say that $\mathcal{I}$ is $\check{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified if it has a locally Leibniz binary reflexive core and an adequate Suszko core and that it is $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified if it has a Leibniz reflexive core and an adequate unary Suszko core. Based on these, we define *syntactic family algebraizability* as the property of being equivalential, family c-reflective and $\check{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and *syntactic family antialgebraizability* as the property of being protoalgebraic, family c-reflective and $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified. For both of these classes of π -institutions we obtain characterizations akin to those obtained for syntactic strong family algebraizability in the first part of the section.

In Section 13.11, we complete the work on syntactic algebraizability started in Section 13.10. We define, here, the three classes of syntactically algebraizable π -institutions that lie between those of the syntactic family algebraizability subhierarchy, introduced in Section 13.10, and those of the syntactic left prealgebraizability subhierarchy, introduced in Section 13.8. We start with the highest class of the syntactic algebraizability hierarchy. We say that a π -institution $\mathcal{I}$ is $\check{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified if its binary reflexive core is locally Leibniz and its unary system core is adequate. $\mathcal{I}$ is *syntactically strongly algebraizable* if it is equivalential, system c-reflective and $\check{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. In terms of lower classes of the syntactic hierarchy, we get that $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is syntactically equivalential and strongly system truth equational. In terms of its semantic counterpart, we obtain that $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is algebraizable and $\check{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. As far as transference of basic proper-

ties, we have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and system c-reflective. With respect to mappings between posets of theory families and of congruence systems, $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism commuting with inverse logical extensions. In terms of equivalences with equational π -structures, $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair of natural transformations. This implies that $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is stable and there exists a transformational order isomorphism $h : \mathbf{ThSys}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$ induced by a conjugate pair of natural transformations, where $\mathcal{Q}$ is an equational π -structure.

In the second part of Section 13.11, we relax the parameterlessness requirements so that two wider classes of syntactic algebraizability, lying below the one studied in the first part, are obtained. We say that a π -institution $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified if it has a locally Leibniz binary reflexive core and an adequate system core, whereas it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified if it has a Leibniz reflexive core and an adequate unary system core. Using these properties, we say that $\mathcal{I}$ is *syntactically algebraizable* if it is equivalential, system c-reflective and $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified. Moreover, $\mathcal{I}$ is *syntactically antialgebraizable* if it is protoalgebraic, system c-reflective and $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. For those two classes, lying below the class of syntactically strongly algebraizable π -institutions, we devise multiple characterizations along similar lines with those presented in the first part of the section for syntactic strong algebraizability.

We provide an overview of the hierarchy of all twelve classes introduced

in this chapter in the accompanying diagram.

13.2 The Binary Reflexive Core

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall that the *reflexive core* of $\mathcal{I}$ is the collection

$$\begin{aligned}
 R^{\mathcal{I}} &= \{ \rho^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \mathbf{SEN}^b(\Sigma))(\rho_{\Sigma}^b[\phi, \phi] \leq \text{Thm}(\mathcal{I})) \} \\
 &= \{ \rho^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi, \tilde{\chi} \in \mathbf{SEN}^b(\Sigma)) \\
 &\quad (\rho_{\Sigma}^b(\phi, \phi, \tilde{\chi}) \subseteq \text{Thm}_{\Sigma}(\mathcal{I})) \}.
 \end{aligned}$$

We define the **binary reflexive core** of $\mathcal{I}$ as the collection

$$B^{\mathcal{I}} : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$$

of binary natural transformations in N^b given by

$$\begin{aligned}
 B^{\mathcal{I}} &= \{ \rho^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \mathbf{SEN}^b(\Sigma))(\rho_{\Sigma}^b[\phi, \phi] \leq \text{Thm}(\mathcal{I})) \} \\
 &= \{ \rho^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \mathbf{SEN}^b(\Sigma))(\rho_{\Sigma}^b(\phi, \phi) \subseteq \text{Thm}_{\Sigma}(\mathcal{I})) \}.
 \end{aligned}$$

Recalling the meaning of $\ddot{R}^{\mathcal{I}}$ from Section 2.15 of Chapter 2, it turns out that the binary reflexive core of $\mathcal{I}$ coincides with the collection $\ddot{R}^{\mathcal{I}}$.

Proposition 957 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $B^{\mathcal{I}} = \ddot{R}^{\mathcal{I}}$.*

Proof: By Theorem 107. ■

In view of Proposition 957, we drop the notation $B^{\mathcal{I}}$ and denote the binary reflexive core of $\mathcal{I}$ by the symbol $\ddot{R}^{\mathcal{I}}$, without fear of ambiguity.

13.3 Syntactic PreEquivalentiality

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Recall from Chapter 5 that $\mathcal{I}$ is *preequivalential* if it is prealgebraic and system extensional, i.e., if:

- For all $T, T' \in \text{ThSys}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T');$$

- For all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle).$$

We say that $\mathcal{I}$ is **syntactically preequivalential** if there exists $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , without parameters, such that I^b has:

- reflexivity;
- global system transitivity;
- global system compatibility; and
- global system modus ponens.

Recall from Chapter 10 that, because all these conditions are imposed on theory systems and because I^b is parameter free, they are all equivalent to the corresponding local properties. Therefore, an equivalent definition would require reflexivity, local system transitivity, local system compatibility and local system modus ponens. Because of this, we sometimes omit the global/local specification and simply say “system” in qualifying the corresponding property.

In case $\mathcal{I}$ is syntactically preequivalential, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of/for the syntactic preequivalentiality of $\mathcal{I}$).

An interesting first observation, that will prove handy later, is that syntactic preequivalentiality is inherited by all π -subinstitutions of a syntactically preequivalential π -institution.

Theorem 958 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ a π -subinstitution of $\mathcal{I}$ induced by the algebraic subsystem $\mathbf{F}' = \langle \mathbf{Sign}^b, \mathbf{SEN}'^b, N'^b \rangle \leq \mathbf{F}$. If $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $I^b \subseteq N^b$, then $\mathcal{I}'$ is also syntactically preequivalential, with witnessing transformations $I'^b \in N'^b$.*

Proof: Suppose that $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$. To prove the conclusion, it suffices to show that I'^b is reflexive, system transitive and has both the system compatibility and the system modus ponens in $\mathcal{I}'$.

Let, first, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}'^b(\Sigma)$. Then, clearly, $I'_\Sigma[\phi, \phi] \leq \text{SEN}'^b$ and $I'_\Sigma[\phi, \phi] = I_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I})$. So we get that

$$I'_\Sigma[\phi, \phi] \leq \text{Thm}(\mathcal{I}) \cap \text{SEN}'^b = \text{Thm}(\mathcal{I}').$$

It follows that I'^b is reflexive in $\mathcal{I}'$.

Suppose, next, that $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}'^b(\Sigma)$, such that

$$I'_\Sigma[\phi, \psi] \leq T \cap \text{SEN}'^b \quad \text{and} \quad I'_\Sigma[\psi, \chi] \leq T \cap \text{SEN}'^b.$$

Then $I_\Sigma^b[\phi, \psi] \leq T$ and $I_\Sigma^b[\psi, \chi] \leq T$, whence, by the global system transitivity of I^b in $\mathcal{I}$, we get that $I_\Sigma^b[\phi, \chi] \leq T$. Since, by hypothesis, $\phi, \chi \in \text{SEN}'^b(\Sigma)$, we get that $I'_\Sigma[\phi, \chi] \leq T \cap \text{SEN}'^b$. This shows that I'^b is globally system transitive in $\mathcal{I}'$.

For system compatibility, let $T \in \text{ThSys}(\mathcal{I})$, $\sigma^b \in N^b$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \tilde{\chi} \in \text{SEN}'^b(\Sigma)$, such that $\vec{I}'_{\Sigma}[\phi, \psi] \leq T \cap \text{SEN}'^b$. Then we get that $\vec{I}_{\Sigma}^b[\phi, \psi] \leq T$, whence, we obtain $I_\Sigma^b[\sigma_\Sigma^b(\phi, \tilde{\chi}), \sigma_\Sigma^b(\psi, \tilde{\chi})] \leq T$. Since $\sigma^b \in N^b$ and $\phi, \psi, \tilde{\chi} \in \text{SEN}'^b(\Sigma)$, this yields that

$$I'_\Sigma[\sigma_\Sigma'^b(\phi, \tilde{\chi}), \sigma_\Sigma'^b(\psi, \tilde{\chi})] \leq T \cap \text{SEN}'^b.$$

Therefore, I'^b has the system compatibility in $\mathcal{I}'$.

For the system MP, assume that $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}'^b(\Sigma)$, such that $\phi \in T_\Sigma \cap \text{SEN}'^b(\Sigma)$ and $I'_\Sigma[\phi, \psi] \leq T \cap \text{SEN}'^b$. Then $\phi \in T_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq T$, whence we get that $\psi \in T_\Sigma$. Since, by hypothesis, $\psi \in \text{SEN}'^b(\Sigma)$, we get that $\psi \in T_\Sigma \cap \text{SEN}'^b(\Sigma)$. Therefore, I'^b has the system MP in $\mathcal{I}'$.

We conclude that $\mathcal{I}'$ is also syntactically preequivalential with witnessing transformations I'^b . ■

Since I^b is, a fortiori, a set of witnessing transformations for the syntactic prealgebraicity of $\mathcal{I}$, we get the following result, based on Corollary 770.

Corollary 959 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations I^b , if and only if, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\begin{array}{c} \xleftarrow{\quad} \\ I^b(T) = \Omega(T). \end{array}$$

Proof: The “only if” is by Corollary 770. The “if” is clear, since the given condition implies that I^b satisfies reflexivity, global system transitivity, global system compatibility and global system modus ponens. ■

Based on Corollary 959, it is easy to see that syntactic preequivalentiality transfers from a π -institution to all gmatrix families of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Theorem 960 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations I^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the $\mathcal{I}$ -gmatrix family $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically preequivalential.*

Proof: The “if” follows by considering the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. For the “only if”, assume that $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations I^b , and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system, $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$. Then, we have

$$\begin{aligned} \langle \alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi) \rangle \in \overleftarrow{I^b}_{F(\Sigma)}(T) & \text{ iff } \overleftrightarrow{I^b}_{F(\Sigma)}[\alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi)] \leq T \\ & \text{ iff } \overleftrightarrow{I^b}_{\Sigma}[\phi, \psi] \leq \alpha^{-1}(T) \\ & \text{ iff } \langle \phi, \psi \rangle \in \Omega_{\Sigma}(\alpha^{-1}(T)) \\ & \text{ iff } \langle \phi, \psi \rangle \in \alpha_{\Sigma}^{-1}(\Omega_{F(\Sigma)}^{\mathcal{A}}(T)) \\ & \text{ iff } \langle \alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi) \rangle \in \Omega_{F(\Sigma)}^{\mathcal{A}}(T). \end{aligned}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, it follows, by Corollary 959, that $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is also syntactically preequivalential, with witnessing transformations $I^{\mathcal{A}}$. ■

It turns out that syntactic preequivalentiality implies preequivalentiality.

Theorem 961 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically preequivalential, then it is preequivalential.*

Proof: Suppose that $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$. Then, it is a fortiori syntactically prealgebraic and, hence, by Theorem 771, prealgebraic. Thus, the Leibniz operator is monotone on theory systems. It suffices, therefore, to show that $\mathcal{I}$ is system extensional. To this end, let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle).$$

Thus, by Theorem 958 and Corollary 959,

$$\overleftrightarrow{I^b}_{\Sigma}[\phi, \psi] \leq T \cap \langle \phi, \psi \rangle.$$

Therefore, $\vec{I}_\Sigma[\phi, \psi] \leq T$, which, again by Corollary 959, implies that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Since, by Proposition 89, the reverse inclusion always holds, $\mathcal{I}$ is also system extensional and, hence, preequivalential. ■

Apart from the definability of Leibniz congruence systems of theory systems, syntactic preequivalentiality has some additional important consequences. Namely, it implies that the binary reflexive core has the system modus ponens and that it also has the extensionality property. Before we look at those results more closely, we give a key lemma to the effect that, in a syntactically preequivalential π -institution, any set of witnessing transformations is included in the binary reflexive core of the π -institution.

Lemma 962 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically preequivalential π -institution, with witnessing transformations $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$. Then $I^b \subseteq \vec{R}^\mathcal{I}$.*

Proof: Since I^b is parameter free and reflexive in $\mathcal{I}$, we get, by definition of $B^\mathcal{I}$ and Proposition 957, that $I^b \subseteq B^\mathcal{I} = \vec{R}^\mathcal{I}$. ■

Now we formalize the fact that syntactic preequivalentiality implies the system modus ponens property for the binary reflexive core.

Proposition 963 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically preequivalential, then $\vec{R}^\mathcal{I}$ has the system modus ponens in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is syntactically preequivalential and let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $\vec{R}_\Sigma^\mathcal{I}[\phi, \psi] \leq T$. Then $\phi \in T_\Sigma$ and, by Lemma 962, $I_\Sigma^b[\phi, \psi] \leq T$. Since I^b has the system MP in $\mathcal{I}$, we conclude that $\psi \in T_\Sigma$. Therefore, $\vec{R}^\mathcal{I}$ has the system MP in $\mathcal{I}$. ■

The next property that is implied by syntactic preequivalentiality is the extensionality of the binary reflexive core. Before introducing the concept, we take a look at a technical lemma that will serve to justify its formulation.

Lemma 964 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $X, Y \in \text{SenSys}(\mathcal{I})$. Then the following conditions are equivalent:*

- (a) *For all $T \in \text{ThFam}(\mathcal{I})$, $X \leq T$ if and only if $Y \leq T$;*
- (b) *For all $T \in \text{ThSys}(\mathcal{I})$, $X \leq T$ if and only if $Y \leq T$.*

Proof: That (a) $\Rightarrow$ (b) is obvious, since every theory system of $\mathcal{I}$ is also a theory family. For (b) $\Rightarrow$ (a), assume that (b) holds and let $T \in \text{ThFam}(\mathcal{I})$, such that $X \leq T$. Then, by Lemma 1, $\overleftarrow{X} \leq \overleftarrow{T}$. Since $X \in \text{SenSys}(\mathcal{I})$, by Proposition 2, we get that $X \leq \overleftarrow{T}$. Therefore, by hypothesis, since $\overleftarrow{T} \in$

$\text{ThSys}(\mathcal{I})$, we obtain $Y \leq \overleftarrow{T} \leq T$. By symmetry, we conclude that, for all $T \in \text{ThFam}(\mathcal{I})$, $X \leq T$ if and only if $Y \leq T$. ■

Due to Lemma 964 and the fact that both the reflexive core and the binary reflexive core yield sentence systems of $\mathcal{I}$ under substitution, we make the following definition (without the need for distinguishing between a family versus a system version).

Definition 965 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. The binary reflexive core $\ddot{R}^{\mathcal{I}}$ is **extensional in $\mathcal{I}$** if and only if, for all $T \in \text{ThSys}(\mathcal{I})$ (or equivalently, by Lemma 964, for all $T \in \text{ThFam}(\mathcal{I})$), all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,*

$$\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T \quad \text{if and only if} \quad R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T.$$

Note that, since, by Lemma 104, $\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq R_{\Sigma}^{\mathcal{I}}[\phi, \psi]$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, the right-to-left implication in Definition 965 always holds. Therefore one has, equivalently, that $\ddot{R}^{\mathcal{I}}$ is extensional if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T \quad \text{implies} \quad R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T.$$

This can be taken to justify the name chosen for this property.

As mentioned previously, and shown in the next proposition, syntactic preequivalentiality implies the extensionality of the binary reflexive core.

Proposition 966 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically preequivalential, then $\ddot{R}^{\mathcal{I}}$ is extensional.*

Proof: Suppose $\mathcal{I}$ is a syntactically preequivalential π -institution, with witnessing transformations $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b . Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$. Then, by Lemma 962, we get that $\vec{I}_{\Sigma}^b[\phi, \psi] \leq T$. Thus, by Corollary 959, we get that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$. Since $\mathcal{I}$ is syntactically preequivalential, it is a fortiori syntactically prealgebraic, whence, by Theorems 781 and 782, we get that $R^{\mathcal{I}}$ is a set of witnessing transformations for the prealgebraicity of $\mathcal{I}$ and, hence, by Theorems 782 and 783, $R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$. Since the reverse inclusion always holds, we conclude that $\ddot{R}^{\mathcal{I}}$ is indeed extensional in $\mathcal{I}$. ■

As a result of preceding work we obtain the following

Theorem 967 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically preequivalential, then $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$.*

Proof: By Propositions 963 and 966. ■

We provide, next, a characterization of syntactic preequivalentiality in terms of the preceding two properties of the binary reflexive core of the π -institution, namely system modus ponens and extensionality. Later, we use this characterization to provide an exact description of those preequivalential π -institutions which are syntactically preequivalential.

In proving the reverse implication of that included in Theorem 967, we now show that, if $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\mathcal{I}$ is syntactically preequivalential.

Theorem 968 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations $\ddot{R}^{\mathcal{I}}$.*

Proof: If $\ddot{R}^{\mathcal{I}}$ has the system MP, then, by Lemma 104, $R^{\mathcal{I}}$ has a fortiori the global system MP. Thus, by Theorem 781, $\mathcal{I}$ is syntactically prealgebraic with witnessing transformations $R^{\mathcal{I}}$. Thus, $R^{\mathcal{I}}$ is globally system reflexive, globally system transitive, has the global system compatibility property and the global system MP. Moreover, by the extensionality of $\ddot{R}^{\mathcal{I}}$, all these properties transfer from $R^{\mathcal{I}}$ to $\ddot{R}^{\mathcal{I}}$. We conclude that $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ■

Theorems 967 and 968 provide the promised characterization of syntactic preequivalentiality in terms of the system modus ponens and the extensionality of the binary reflexive core.

$$\begin{aligned} \mathcal{I} \text{ is Syntactically Preequivalential} &\longleftrightarrow \ddot{R}^{\mathcal{I}} \text{ has System MP} \\ &+ \ddot{R}^{\mathcal{I}} \text{ is Extensional.} \end{aligned}$$

Theorem 969 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically preequivalential if and only if $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$.*

Proof: Theorem 967 gives the “only if” and the “if” is by Theorem 968. ■

If $\mathcal{I}$ is syntactically preequivalential, then $\ddot{R}^{\mathcal{I}}$ defines Leibniz congruence systems of theory systems in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 959, since $\ddot{R}^{\mathcal{I}}$ forms a set of witnessing transformations.

Proposition 970 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T).$$

Proof: Let $T \in \text{ThSys}(\mathcal{I})$. If $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional, then, by Theorem 968, $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Therefore, by Corollary 959, for all $T \in \text{ThSys}(\mathcal{I})$, $\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T)$. ■

We also get another related characterization of syntactic preequivalentiality.

$$\begin{aligned} \mathcal{I} \text{ is Syntactically Preequivalential} \\ \longleftrightarrow \ddot{R}^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ \text{of Theory Systems in } \mathcal{I}. \end{aligned}$$

Theorem 971 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically preequivalential if and only if, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T).$$

Proof: If $\mathcal{I}$ is syntactically preequivalential, then, by Theorem 967, $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$. Thus, by Proposition 970, for all $T \in \text{ThSys}(\mathcal{I})$, $\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T)$.

Conversely, if, for all $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{\ddot{R}^{\mathcal{I}}}(T) = \Omega(T)$, then, $\ddot{R}^{\mathcal{I}}$ is reflexive, system transitive, has the system compatibility and the system modus ponens. Thus, $\mathcal{I}$ is syntactically preequivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ■

We finally show that the property that separates preequivalentiality from syntactic preequivalentiality is exactly a sort of a local Leibniz compatibility property with respect to the theory system generated by the binary reflexive core.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall that $R^{\mathcal{I}}$ is *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])).$$

Similarly, we say that $\ddot{R}^{\mathcal{I}}$ is **locally Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{(\phi, \psi)}(C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

We show next that, if $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is locally Leibniz.

Proposition 972 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is locally Leibniz.*

Proof: Suppose that $\ddot{R}^{\mathcal{I}}$ has the system MP and is extensional and let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. By Theorem 968, $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Hence, it is a fortiori syntactically prealgebraic, with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Thus, by Theorem 788, we get

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])).$$

Then, by Theorem 89, we get

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{(\phi, \psi)}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

By hypothesis (more precisely the extensionality of $\ddot{R}^{\mathcal{I}}$), we get $C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]) = C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi])$. Therefore, we conclude that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{(\phi, \psi)}(C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \cap \langle \phi, \psi \rangle)$. So $\ddot{R}^{\mathcal{I}}$ is locally Leibniz. ■

In the opposite direction, in a preequivalential π -institution $\mathcal{I}$, if the binary reflexive core is locally Leibniz, then it has the system modus ponens and is extensional in $\mathcal{I}$.

Proposition 973 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a preequivalential π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ is locally Leibniz, then $\ddot{R}^{\mathcal{I}}$ has the system modus ponens and is extensional in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is preequivalential and that $\ddot{R}^{\mathcal{I}}$ is locally Leibniz.

For the system MP, suppose that $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_{\Sigma}$, $\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$. Then, since $\ddot{R}^{\mathcal{I}}$ is locally Leibniz,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{(\phi, \psi)}(C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

Thus, since $\mathcal{I}$ is system extensional,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi])).$$

By hypothesis, $C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \leq T$, whence, by preequivalentiality,

$$\Omega(C(\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi])) \leq \Omega(T).$$

We, thus, get that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$. Therefore, by compatibility of $\Omega(T)$ with T , we obtain $\psi \in T_{\Sigma}$, showing that $\ddot{R}^{\mathcal{I}}$ has the system MP in $\mathcal{I}$.

For extensionality, assume that $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\ddot{R}_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$. Following the initial argument of the preceding paragraph mutatis mutandis, we obtain that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$. But since $\ddot{R}^{\mathcal{I}}$ has the system MP, a fortiori $R^{\mathcal{I}}$ has the global system MP, whence, by Proposition 783, $R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$. Since the reverse inclusion always holds, we conclude that $\ddot{R}^{\mathcal{I}}$ is extensional. ■

We now show that a π -institution is syntactically preequivalential if and only if it is preequivalential and it has a locally Leibniz binary reflexive core.

Syntactic Preequivalentiality

- = $\ddot{R}^{\mathcal{I}}$ has System MP + $\ddot{R}^{\mathcal{I}}$ is Extensional
- = $\ddot{R}^{\mathcal{I}}$ Defines Leibniz Congruence Systems of Theory Systems in $\mathcal{I}$
- = Preequivalentiality + $\ddot{R}^{\mathcal{I}}$ is Locally Leibniz

Theorem 974 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically preequivalential if and only if it is preequivalential and has a locally Leibniz binary reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically preequivalential. Then it is preequivalential by Theorem 961. Moreover, its binary reflexive core has the system modus ponens and is extensional, by Theorem 969, and, hence, by Proposition 972, its binary reflexive core is locally Leibniz.

Suppose, conversely, that $\mathcal{I}$ is preequivalential with a locally Leibniz binary reflexive core. Then, by Proposition 973, its binary reflexive core has the system MP and is extensional. Therefore, by Theorem 969, $\mathcal{I}$ is syntactically preequivalential. ■

We have the following part of a hierarchy:

13.4 Syntactic Equivalentiality

We now define the class of syntactically equivalential π -institutions. The difference between equivalentiality and preequivalentiality is that the system versions of the properties defining the latter are replaced by their corresponding family versions. Otherwise, the developments are exactly parallel.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$.

Recall from Chapter 5 that $\mathcal{I}$ is *equivalential* if it is protoalgebraic and family extensional, i.e., if:

- For all $T, T' \in \text{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T');$$

- For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(T \cap \langle \phi, \psi \rangle).$$

Recall, also, that, by Theorem 175, protoalgebraicity implies stability. If a π -institution is stable, then, by Proposition 309, it is family extensional if and only if it is system extensional. Thus, under protoalgebraicity, system and family extensionality coincide, and, therefore, $\mathcal{I}$ being equivalential is equivalent to $\mathcal{I}$ being protoalgebraic and system extensional.

We say that $\mathcal{I}$ is **syntactically equivalential** if there exists $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b , without parameters, such that I^b has:

- reflexivity;
- global family transitivity;
- global family compatibility; and
- global family modus ponens.

We emphasize that, as opposed to the case of the corresponding system properties, in this case, the latter three conditions are not equivalent to the corresponding local properties. So one cannot dispense with the qualification “global” in the defining conditions.

In case $\mathcal{I}$ is syntactically equivalential, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic equivalentiality of $\mathcal{I}$).

As a consequence of Theorem 912, we obtain the following corollary, relating the existence of a conjugate pair of natural transformations and syntactic equivalentiality.

Corollary 975 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$ an equational π -structure. If $\mathcal{I}$ is equivalent to $\mathcal{Q}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$ of natural transformations, then $\mathcal{I}$ is syntactically equivalential with witnessing transformations I^b .*

Proof: By Theorem 912, $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations I^b . Since $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ is parameter free, we conclude that $\mathcal{I}$ is syntactically equivalential with witnessing transformations I^b . ■

As was the case with syntactic preequivalentiality, syntactic equivalentiality is inherited by all π -subinstitutions of a syntactically equivalential π -institution.

Theorem 976 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{I}' = \langle \mathbf{F}', C' \rangle$ a π -subinstitution of $\mathcal{I}$ induced by the algebraic subsystem $\mathbf{F}' = \langle \mathbf{Sign}^b, \mathbf{SEN}'^b, N'^b \rangle \leq \mathbf{F}$. If $\mathcal{I}$ is syntactically equivalential with witnessing transformations $I^b \subseteq N^b$, then $\mathcal{I}'$ is also syntactically equivalential, with witnessing transformations $I'^b \in N'^b$.*

Proof: Suppose that $\mathcal{I}$ is syntactically equivalential with witnessing transformations $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$. To prove the conclusion, it suffices to show that I'^b is reflexive, globally family transitive and has both the global family compatibility and the global family modus ponens in $\mathcal{I}'$.

Let, first, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}'^b(\Sigma)$. Then, clearly, $I'_\Sigma[\phi, \phi] \leq \mathbf{SEN}'^b$ and $I'_\Sigma[\phi, \phi] = I_\Sigma^b[\phi, \phi] \leq \mathbf{Thm}(\mathcal{I})$. So we get that

$$I'_\Sigma[\phi, \phi] \leq \mathbf{Thm}(\mathcal{I}) \cap \mathbf{SEN}'^b = \mathbf{Thm}(\mathcal{I}').$$

It follows that I'^b is reflexive in $\mathcal{I}'$.

Suppose, next, that $T \in \mathbf{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}'^b(\Sigma)$, such that

$$I_\Sigma^b[\phi, \psi] \leq T \cap \mathbf{SEN}'^b \quad \text{and} \quad I_\Sigma^b[\psi, \chi] \leq T \cap \mathbf{SEN}'^b.$$

Then $I_\Sigma^b[\phi, \psi] \leq T$ and $I_\Sigma^b[\psi, \chi] \leq T$, whence by the global family transitivity of I^b in $\mathcal{I}$, we get that $I_\Sigma^b[\phi, \chi] \leq T$. Since, by hypothesis, $\phi, \chi \in \mathbf{SEN}'^b(\Sigma)$, we get that $I'_\Sigma[\phi, \chi] \leq T \cap \mathbf{SEN}'^b$. This shows that I'^b is globally family transitive in $\mathcal{I}'$.

For global family compatibility, let $T \in \mathbf{ThFam}(\mathcal{I})$, $\sigma^b \in N^b$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \vec{\chi} \in \mathbf{SEN}'^b(\Sigma)$, such that $\vec{I}^b_\Sigma[\phi, \psi] \leq T \cap \mathbf{SEN}'^b$. Then we get that $\vec{I}^b_\Sigma[\phi, \psi] \leq T$, whence, we obtain $I_\Sigma^b[\sigma_\Sigma^b(\phi, \vec{\chi}), \sigma_\Sigma^b(\psi, \vec{\chi})] \leq T$. Since $\sigma^b \in N^b$ and $\phi, \psi, \vec{\chi} \in \mathbf{SEN}'^b(\Sigma)$, this yields that

$$I'_\Sigma[\sigma'_\Sigma(\phi, \vec{\chi}), \sigma'_\Sigma(\psi, \vec{\chi})] \leq T \cap \mathbf{SEN}'^b.$$

Therefore, I'^b has the global family compatibility in $\mathcal{I}'$.

For the global family MP, assume that $T \in \mathbf{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}'^b(\Sigma)$, such that $\phi \in T_\Sigma \cap \mathbf{SEN}'^b(\Sigma)$ and $I'_\Sigma[\phi, \psi] \leq T \cap \mathbf{SEN}'^b$. Then $\phi \in T_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq T$, whence we get that $\psi \in T_\Sigma$. Since, by hypothesis, $\psi \in \mathbf{SEN}'^b(\Sigma)$, we get that $\psi \in T_\Sigma \cap \mathbf{SEN}'^b(\Sigma)$. Therefore, I'^b has the global family MP in $\mathcal{I}'$.

We conclude that $\mathcal{I}'$ is also syntactically equivalential with witnessing transformations I'^b . ■

Since I^b is, a fortiori, a set of witnessing transformations for the syntactic protoalgebraicity of $\mathcal{I}$, we get the following result, based on Corollary 791.

Corollary 977 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential, with witnessing transformations I^b , if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overset{\leftarrow}{\overset{\rightarrow}{I^b}}(T) = \Omega(T).$$

Proof: The “only if” is by Corollary 791. The “if” is clear, since the given condition implies that $\overset{\rightarrow}{I^b}$ satisfies reflexivity, global family transitivity, global family compatibility and global family modus ponens. ■

Based on Corollary 977, it is easy to see that syntactic equivalentiality also transfers from a π -institution to all gmatrix families of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.

Theorem 978 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential, with witnessing transformations I^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the $\mathcal{I}$ -gmatrix family $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically equivalential.*

Proof: Analogous to the proof of Theorem 960. ■

Syntactic equivalentiality implies equivalentiality.

Theorem 979 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically equivalential, then it is equivalential.*

Proof: Suppose that $\mathcal{I}$ is syntactically equivalential, with witnessing transformations $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$. Then, it is a fortiori syntactically protoalgebraic and, hence, by Theorem 792, protoalgebraic. Thus, the Leibniz operator is monotone on theory families. Since syntactic equivalentiality implies syntactic preequivalentiality, by Theorem 961, we get that $\mathcal{I}$ is also system extensional. ■

In analogy with syntactic preequivalentiality, syntactic equivalentiality implies that the binary reflexive core has the global family modus ponens and that it also has the extensionality property.

We first formalize the fact that syntactic equivalentiality implies the global family modus ponens property of the binary reflexive core.

Proposition 980 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically equivalential, then $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is syntactically equivalential, with witnessing transformations I^b , and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $\ddot{R}_\Sigma^\mathcal{I}[\phi, \psi] \leq T$. Then $\phi \in T_\Sigma$ and, by Lemma 962, $I_\Sigma^b[\phi, \psi] \leq T$. Since I^b has the global family MP in $\mathcal{I}$, we conclude that $\psi \in T_\Sigma$. Therefore, $\ddot{R}^\mathcal{I}$ also has the global family MP in $\mathcal{I}$. ■

We now show that syntactic equivalentiality implies the extensionality of the binary reflexive core.

Corollary 981 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically equivalential, then $\ddot{R}^\mathcal{I}$ is extensional.*

Proof: Since syntactic equivalentiality implies syntactic preequivalentiality, we get the conclusion by applying Proposition 966. ■

We summarize these two important consequences of syntactic equivalentiality in the following

Theorem 982 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically equivalential, then $\ddot{R}^\mathcal{I}$ has the global family modus ponens and is extensional in $\mathcal{I}$.*

Proof: By Propositions 980 and 981. ■

We provide, next, a characterization of syntactic equivalentiality in terms of the preceding two properties of the binary reflexive core of the π -institution, namely global family modus ponens and extensionality. As with preequivalentiality, we use this characterization to provide an exact description of those equivalential π -institutions which are syntactically equivalential.

In proving the reverse implication of that included in Theorem 982, we show that, if $\ddot{R}^\mathcal{I}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then $\mathcal{I}$ is syntactically equivalential.

Theorem 983 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\ddot{R}^\mathcal{I}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then $\mathcal{I}$ is syntactically equivalential, with witnessing transformations $\ddot{R}^\mathcal{I}$.*

Proof: If $\ddot{R}^\mathcal{I}$ has the global family MP, then, by Lemma 104, $R^\mathcal{I}$ has a fortiori the global family MP. Thus, by Theorem 798, $\mathcal{I}$ is syntactically protoalgebraic with witnessing transformations $R^\mathcal{I}$. Thus, $R^\mathcal{I}$ is reflexive, globally family transitive, has the global family compatibility property and the global family MP. Moreover, by the extensionality of $\ddot{R}^\mathcal{I}$, all these properties transfer from $R^\mathcal{I}$ to $\ddot{R}^\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically equivalential with witnessing transformations $\ddot{R}^\mathcal{I}$. ■

Theorems 982 and 983 provide the promised characterization of syntactic equivalentiality in terms of the global family modus ponens and the extensionality of the binary reflexive core.

$$\mathcal{I} \text{ is Syntactically Equivalential} \iff \begin{array}{l} \ddot{R}^{\mathcal{I}} \text{ has Global Family MP} \\ + \ddot{R}^{\mathcal{I}} \text{ is Extensional.} \end{array}$$

Theorem 984 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential if and only if $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$.*

Proof: Theorem 982 gives the “only if” and the “if” is by Theorem 983. ■

If $\mathcal{I}$ is syntactically equivalential, then $\ddot{R}^{\mathcal{I}}$ defines Leibniz congruence systems of theory families in $\mathcal{I}$. This proposition may be viewed as a special case of Corollary 977, since $\ddot{R}^{\mathcal{I}}$ forms a set of witnessing transformations.

Proposition 985 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T).$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$. If $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional, then, by Theorem 983, $\mathcal{I}$ is syntactically equivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. Therefore, by Corollary 977, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T)$. ■

We also get another related characterization of syntactic equivalentiality.

$$\begin{array}{l} \mathcal{I} \text{ is Syntactically Equivalential} \\ \iff \ddot{R}^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ \text{of Theory Families in } \mathcal{I}. \end{array}$$

Theorem 986 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T).$$

Proof: If $\mathcal{I}$ is syntactically equivalential, then, by Theorem 982, $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$. Thus, by Proposition 985, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \overleftarrow{\ddot{R}^{\mathcal{I}}}(T)$.

Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{\ddot{R}^{\mathcal{I}}}(T) = \Omega(T)$, then, $\ddot{R}^{\mathcal{I}}$ is reflexive, globally family transitive and has the global family compatibility and

the global family modus ponens. Thus, $\mathcal{I}$ is syntactically equivalential with witnessing transformations $\ddot{R}^{\mathcal{I}}$. ■

We finally show that the property that separates equivalentiality from syntactic equivalentiality is the local Leibniz property of the binary reflexive core.

We show first that, if $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is locally Leibniz.

Corollary 987 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$, then $\ddot{R}^{\mathcal{I}}$ is locally Leibniz.*

Proof: Since $\ddot{R}^{\mathcal{I}}$ having the global family MP is stronger than having the system MP, the conclusion follows from Proposition 972. ■

In the opposite direction, in an equivalential π -institution $\mathcal{I}$, if the binary reflexive core is locally Leibniz, then it has the global family modus ponens and is extensional in $\mathcal{I}$.

Proposition 988 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ an equivalential π -institution based on $\mathbf{F}$. If $\ddot{R}^{\mathcal{I}}$ is locally Leibniz, then $\ddot{R}^{\mathcal{I}}$ has the global family modus ponens and is extensional in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}$ is equivalential and that $\ddot{R}^{\mathcal{I}}$ is locally Leibniz.

For the global family MP, suppose that $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$, $\ddot{R}_\Sigma^{\mathcal{I}}[\phi, \psi] \leq T$. Then, since $\ddot{R}^{\mathcal{I}}$ is locally Leibniz,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma^{\langle \phi, \psi \rangle}(C(\ddot{R}_\Sigma^{\mathcal{I}}[\phi, \psi]) \cap \langle \phi, \psi \rangle).$$

Thus, since $\mathcal{I}$ is system extensional,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(\ddot{R}_\Sigma^{\mathcal{I}}[\phi, \psi])).$$

By hypothesis, $C(\ddot{R}_\Sigma^{\mathcal{I}}[\phi, \psi]) \leq T$, whence, by equivalentiality,

$$\Omega(C(\ddot{R}_\Sigma^{\mathcal{I}}[\phi, \psi])) \leq \Omega(T).$$

We, thus, get that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, by compatibility of $\Omega(T)$ with T , we obtain $\psi \in T_\Sigma$, showing that $\ddot{R}^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$.

Since equivalentiality implies preequivalentiality, the extensionality of $\ddot{R}^{\mathcal{I}}$ follows from Proposition 973. ■

We now show that a π -institution is syntactically equivalential if and only if it is equivalential and has a locally Leibniz binary reflexive core.

Syntactic Equivalentiality

$$\begin{aligned} &= \ddot{R}^{\mathcal{I}} \text{ has Global Family MP} + \ddot{R}^{\mathcal{I}} \text{ is Extensional} \\ &= \ddot{R}^{\mathcal{I}} \text{ Defines Leibniz Congruence Systems} \\ &\quad \text{of Theory Families in } \mathcal{I} \\ &= \text{Equivalentiality} + \ddot{R}^{\mathcal{I}} \text{ is Locally Leibniz} \end{aligned}$$

Theorem 989 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically equivalential if and only if it is equivalential and has a locally Leibniz binary reflexive core.*

Proof: Suppose, first, that $\mathcal{I}$ is syntactically equivalential. Then it is equivalential by Theorem 979. Moreover, its binary reflexive core has the global family modus ponens and is extensional, by Theorem 984, and, hence, by Corollary 987, its binary reflexive core is locally Leibniz.

Suppose, conversely, that $\mathcal{I}$ is equivalential with a locally Leibniz binary reflexive core. Then, by Proposition 988, its binary reflexive core has the global family MP and is extensional. Therefore, by Theorem 984, $\mathcal{I}$ is syntactically equivalential. ■

We have now established the following hierarchy of properties:

We give an example of a syntactically preequivalential π -institution which is not syntactically equivalential.

Example 990 EXAMPLE NOT FOUND YET!!

13.5 Strong Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is **strongly (family) truth equational** if there exists a set $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ in N^b (with a single distinguished argument), such that, for every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

In that case, we call τ^b a **set of witnessing equations** (of/for the strong truth equationality of $\mathcal{I}$).

Note that, since τ^b is parameter-free and $\Omega(T)$ is invariant under signature morphisms, strong truth equationality may be defined equivalently by the condition, for every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b(\phi) \subseteq \Omega_\Sigma(T).$$

Since truth equationality implies systemicity (see comments at the beginning of Section 11.8), we get, a fortiori, that strong truth equationality implies systemicity.

We introduce next the unary Suszko core of a π -institution. Analogously with the Suszko core, the unary Suszko core enables one to obtain:

- A characterization of strong truth equationality in terms of the solubility property of the unary Suszko core of the π -institution.
- An exact description of those family c-reflective π -institutions which are strongly truth equational.
- A characterization of those truth equational π -institutions which are strongly truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **unary Suszko core** of $\mathcal{I}$ is the collection

$$\dot{S}^\mathcal{I} = \{ \sigma^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2 \in N^b : (\forall T \in \text{ThFam}(\mathcal{I}))(\sigma^b[T] \leq \tilde{\Omega}^\mathcal{I}(T)) \}.$$

By Lemma 822, this definition is equivalent to setting

$$\begin{aligned} \dot{S}^\mathcal{I} = \{ \sigma^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2 \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|) \\ (\forall \phi \in \text{SEN}^b(\Sigma))(\sigma_\Sigma^b(\phi) \in \tilde{\Omega}_\Sigma^\mathcal{I}(C(\phi))) \}. \end{aligned}$$

Note that the unary Suszko core of a π -institution is included in the Suszko core, i.e., we have

Lemma 991 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $\dot{S}^\mathcal{I} \subseteq S^\mathcal{I}$.*

Proof: Every pair of unary natural transformations in N^b that satisfies the membership criterion for $\dot{S}^\mathcal{I}$ also satisfies the condition for membership in $S^\mathcal{I}$. ■

Lemma 991 yields immediately the following consequence.

Corollary 992 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$, we have*

$$\overleftarrow{S}^\mathcal{I}(\Omega(T)) \leq \overleftarrow{S}^\mathcal{I}(\Omega(T)).$$

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \overleftarrow{S}^{\mathcal{I}}_{\Sigma}(\Omega(T)) & \quad \text{iff} \quad S^{\mathcal{I}}_{\Sigma}[\phi] \leq \Omega(T) \quad (\text{definition}) \\ & \quad \text{implies} \quad \dot{S}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad (\text{Lemma 991}) \\ & \quad \text{iff} \quad \phi \in \overleftarrow{\dot{S}}^{\mathcal{I}}_{\Sigma}(\Omega(T)). \quad (\text{definition}) \end{aligned}$$

Therefore, $\overleftarrow{S}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{\dot{S}}^{\mathcal{I}}(\Omega(T))$. ■

Either directly by the definition or using Proposition 833 together with Corollary 992, we get the following

Proposition 993 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $T \in \text{ThFam}(\mathcal{I})$,*

$$T \leq \overleftarrow{\dot{S}}^{\mathcal{I}}(\Omega(T)).$$

Proof: We have $T \leq \overleftarrow{S}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{\dot{S}}^{\mathcal{I}}(\Omega(T))$, where the first inclusion is by Lemma 833 and the second by Corollary 992. ■

Similarly with the Suszko core, the unary Suszko core of a π -institution may or may not satisfy the reverse inclusion of Proposition 993, a property that was called *solubility*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the unary Suszko core of $\mathcal{I}$ is **soluble** if, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\overleftarrow{\dot{S}}^{\mathcal{I}}(\Omega(T)) \leq T.$$

Note that $\dot{S}^{\mathcal{I}}$ is soluble if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\dot{S}^{\mathcal{I}}_{\Sigma}(\phi) \subseteq \Omega_{\Sigma}(T) \quad \text{implies} \quad \phi \in T_{\Sigma}.$$

It turns out that possession of the solubility property by the unary Suszko core intrinsically characterizes strong truth equationality. To show the necessity of solubility observe, first, that, in case a π -institution is strongly truth equational, the witnessing equations form a subset of the unary Suszko core.

Lemma 994 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly truth equational, with witnessing equations $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ in N^b , then $\tau^b \subseteq \dot{S}^{\mathcal{I}}$.*

Proof: Suppose that $\mathcal{I}$ is strongly truth equational with witnessing equations τ^b . Then, $\mathcal{I}$ is, a fortiori, truth equational, with the same witnessing equations. It follows, by Lemma 836, that $\tau^b \subseteq S^{\mathcal{I}}$. Since τ^b consists of unary equations and they satisfy the membership criterion for $S^{\mathcal{I}}$, it follows that they also satisfy the condition for membership in $\dot{S}^{\mathcal{I}}$. Therefore, we get that $\tau^b \subseteq \dot{S}^{\mathcal{I}}$. ■

Now we prove the necessity of the solubility of the unary Suszko core for strong truth equationality.

Theorem 995 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly truth equational, then $\dot{S}^{\mathcal{I}}$ is soluble.*

Proof: Suppose that $\mathcal{I}$ is strongly truth equational, with witnessing equations $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) & \text{ implies } \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{Lemma 994}) \\ & \text{ iff } \phi \in T_{\Sigma}. \quad (\text{strong truth equationality}) \end{aligned}$$

Thus, $\dot{S}^{\mathcal{I}}$ is soluble. ■

The reverse implication also holds and completes the promised characterization of strong truth equationality in terms of the solubility of the unary Suszko core.

Theorem 996 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is soluble, then $\mathcal{I}$ is strongly truth equational, with witnessing equations $\dot{S}^{\mathcal{I}}$.*

Proof: It suffices to show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 993, whereas the converse is ensured by the postulated solubility of $\dot{S}^{\mathcal{I}}$. ■

Theorems 995 and 996 provide the promised characterization of strong truth equationality in terms of the solubility of the unary Suszko core.

$$\mathcal{I} \text{ is Strongly Truth Equational} \longleftrightarrow \dot{S}^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 997 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly truth equational if and only if $\dot{S}^{\mathcal{I}}$ is soluble.*

Proof: Theorem 995 gives the “only if” and the “if” is by Theorem 996. ■

If $\mathcal{I}$ is strongly truth equational, then the unary Suszko core defines theory families in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 829, since $\dot{S}^{\mathcal{I}}$ forms a maximal set of witnessing equations of the strong truth equationality of $\mathcal{I}$.

Proposition 998 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is soluble, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$T = \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\dot{S}^{\mathcal{I}}$ is soluble, then, by Theorem 996, $\dot{S}^{\mathcal{I}}$ forms a set of witnessing equations for the strong truth equationality of $\mathcal{I}$. Therefore, by Proposition 829, we get that, for every $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T))$. ■

This property provides another characterization of strong truth equationality. We say that $\dot{S}^{\mathcal{I}}$ **defines theory families** if, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T))$. Then we have:

$\mathcal{I}$ is Strongly Truth Equational $\longleftrightarrow \dot{S}^{\mathcal{I}}$ Defines Theory Families.

Theorem 999 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly truth equational if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$T = \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is truth equational, then, by Theorem 997, $\dot{S}^{\mathcal{I}}$ is soluble. Thus, by Proposition 998, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T))$.

Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \overleftarrow{\dot{S}^{\mathcal{I}}}(\Omega(T))$, then, $\dot{S}^{\mathcal{I}}$ is soluble. Thus, again by Theorem 997, $\dot{S}^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is strongly truth equational. ■

It turns out that the property that separates family complete reflectivity from strong truth equationality is exactly the adequacy property of the unary Suszko core. Roughly speaking, this property ensures that the unary Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

We have the following relationship connecting the unary Suszko core with both Leibniz and Suszko congruence systems.

Proposition 1000 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, we have, using Lemma 991,

$$S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

Therefore, $\{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \subseteq \{ \Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}$. We conclude that

$$\bigcap \{ \Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)),$$

where the last inclusion is based on Proposition 842. ■

Again it is possible, but not necessary, that the unary Suszko core of a π -institution satisfies, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, the reverse inclusion of that given in Proposition 1000:

$$\tilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \bigcap \{\Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\}.$$

Intuitively speaking, this means that the unary Suszko core $\dot{S}^{\mathcal{I}}$ is rich enough to allow, for every Σ -sentence ϕ , the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\phi)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the unary Suszko core $\dot{S}^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap \{\Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\}.$$

Based on our preceding work, it is not difficult to see that, if $\dot{S}^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 1001 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(C(\phi)) &= \bigcap \{\Omega(T) : \phi \in T_{\Sigma}\} \quad (\text{definition of } \tilde{\Omega}^{\mathcal{I}}(C(\phi))) \\ &= \bigcap \{\Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\}. \\ &\quad (\text{solubility of } \dot{S}^{\mathcal{I}} \text{ and Proposition 998}) \end{aligned}$$

We conclude that $\dot{S}^{\mathcal{I}}$ is adequate. ■

In the opposite direction, in a *family c-reflective* π -institution $\mathcal{I}$, if the unary Suszko core is adequate, then it is also soluble.

Proposition 1002 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a family c-reflective π -institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is family c-reflective and that $\dot{S}^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 993. For the converse, assume that $\dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by the adequacy of $\dot{S}^{\mathcal{I}}$, we get that $\tilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \Omega(T)$. Thus, by family c-reflectivity and Lemma 827, we conclude that $C(\phi) \leq T$, which gives $\phi \in T_{\Sigma}$. ■

We finally show that a π -institution is strongly truth equational if and only if it is family c-reflective and has an adequate unary Suszko core.

$$\begin{aligned} \text{Strong Truth Equationality} &= \dot{S}^{\mathcal{I}} \text{ Soluble} \\ &= \dot{S}^{\mathcal{I}} \text{ Defines Theory Families} \\ &= \text{Family c-Reflectivity} + \dot{S}^{\mathcal{I}} \text{ Adequate} \end{aligned}$$

Theorem 1003 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly truth equational if and only if it is family c-reflective and has an adequate unary Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly truth equational. Then, by Theorem 830, it is family c-reflective. Moreover, by Theorem 997, its unary Suszko core is soluble and, hence, by Corollary 1001, its unary Suszko core is adequate.

Suppose, conversely, that $\mathcal{I}$ is family c-reflective with an adequate unary Suszko core. Then, by Proposition 1002, its unary Suszko core is soluble and, therefore, by Theorem 997, $\mathcal{I}$ is strongly truth equational. ■

We close the section with a result relating the unary Suszko core with the Suszko core. More precisely, we show that adequacy of the unary Suszko core implies adequacy of the Suszko core.

Proposition 1004 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{S}^{\mathcal{I}}$ is adequate, then $S^{\mathcal{I}}$ is adequate.*

Proof: Suppose that $\dot{S}^{\mathcal{I}}$ is adequate. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(C(\phi)) &\leq \cap \{ \Omega(T) : \dot{S}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \quad (\dot{S}^{\mathcal{I}} \text{ adequate}) \\ &\leq \cap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \quad (\dot{S}^{\mathcal{I}} \subseteq S^{\mathcal{I}}) \\ &\leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)). \quad (\text{Proposition 842}) \end{aligned}$$

Hence, $\tilde{\Omega}^{\mathcal{I}}(C(\phi)) = \cap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}$, and $S^{\mathcal{I}}$ is adequate. ■

13.6 Strong Left Truth Equationality

We now undertake the study of strong left truth equationality. This combines, in a certain sense, the study of left truth equationality with that of strong truth equationality. Strong left truth equationality has the same relation to left truth equationality as strong truth equationality has to (family) truth equationality. After this study, we will have the following hierarchy

of truth equationality properties, which will be further augmented in the following section by adjoining strong system truth equationality:

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is **strongly left truth equational** if there exists a set $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ in N^b (with a single distinguished argument), such that, for every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

In that case, we call τ^b a **set of witnessing equations** (of the strong left truth equationality of $\mathcal{I}$).

Note that, similarly to strong truth equationality, since τ^b is parameter free and $\Omega(T)$ is invariant under signature morphisms, strong left truth equationality may be defined equivalently by the condition, for every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b(\phi) \subseteq \Omega_\Sigma(T).$$

Recall that strong truth equationality implies systemicity. Therefore, if a π -institution $\mathcal{I}$ is strongly truth equational, we get, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T),$$

whence $\mathcal{I}$ is also strongly left truth equational.

We introduce next the unary left Suszko core of a π -institution. Analogously with the left Suszko core and the unary Suszko core, the unary left Suszko core enables one to obtain:

- A characterization of strong left truth equationality in terms of the solubility property of the unary left Suszko core of the π -institution.

- An exact description of those left c-reflective π -institutions which are strongly left truth equational.
- A characterization of those left truth equational π -institutions which are strongly left truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **unary left Suszko core** of $\mathcal{I}$ is the collection

$$\dot{L}^{\mathcal{I}} = \{ \sigma^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2 \in N^b : (\forall T \in \text{ThFam}(\mathcal{I})) (\sigma^b[\overleftarrow{T}] \leq \tilde{\Omega}^{\mathcal{I}}(T)) \}.$$

There are a couple of different possible characterizations of the unary left Suszko core that can be given. One is in terms of theory systems in place of theory families and another uses theory systems generated by single sentences.

Proposition 1005 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$\dot{L}^{\mathcal{I}} = \{ \sigma^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2 \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)) \}.$$

Proof: By Proposition 853, we have that

$$L^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T)) \}.$$

Thus, the conclusion follows by applying the $\dot{}$ operator on both sides, i.e., by intersecting both sides with the set of all pairs of unary natural transformations in N^b . ■

With Proposition 1005 at hand, the second characterization follows from Lemma 823.

Corollary 1006 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$\begin{aligned} \dot{L}^{\mathcal{I}} = \{ \sigma^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2 \in N^b : & (\forall \Sigma \in |\mathbf{Sign}^b|) \\ & (\forall \phi \in \mathbf{SEN}^b(\Sigma)) (\sigma_{\Sigma}^b(\phi) \in \tilde{\Omega}_{\Sigma}^{\mathcal{I}}(C(\overrightarrow{\phi}))) \}. \end{aligned}$$

Proof: By combining Proposition 1005 with Lemma 823. ■

Note that the unary left Suszko core of a π -institution is included in the left Suszko core, i.e., we have

Lemma 1007 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $\dot{L}^{\mathcal{I}} \subseteq L^{\mathcal{I}}$.*

Proof: Every pair of unary natural transformations in N^b that satisfies the membership criterion for $\dot{L}^{\mathcal{I}}$ also satisfies the condition for membership in $L^{\mathcal{I}}$. ■

Lemma 1007 yields immediately the following consequence.

Corollary 1008 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$, we have*

$$\overleftarrow{L}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{\dot{L}}^{\mathcal{I}}(\Omega(T)).$$

Proof: By Theorem 107 and Corollary 105. ■

Either directly by the definition or using Proposition 854 together with Corollary 1008, we get the following

Proposition 1009 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} \leq \overleftarrow{\dot{L}}^{\mathcal{I}}(\Omega(T)).$$

Proof: We have $\overleftarrow{T} \leq \overleftarrow{L}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{\dot{L}}^{\mathcal{I}}(\Omega(T))$, where the first inclusion is by Lemma 854 and the second by Corollary 1008. ■

Similarly with the left Suszko core, the unary left Suszko core of a π -institution may or may not satisfy the reverse inclusion of Proposition 1009, a property that was called left solubility.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the unary left Suszko core of $\mathcal{I}$ is **left soluble** if, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\overleftarrow{\dot{L}}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{T}.$$

Note that $\dot{L}^{\mathcal{I}}$ is left soluble if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\dot{L}_{\Sigma}^{\mathcal{I}}(\phi) \subseteq \Omega_{\Sigma}(T) \quad \text{implies} \quad \phi \in \overleftarrow{T}_{\Sigma}.$$

It turns out that possession of left solubility by the unary left Suszko core intrinsically characterizes strong left truth equationality. To show the necessity of left solubility observe, first, that, in case a π -institution is strongly left truth equational, the witnessing equations form a subset of the unary left Suszko core.

Lemma 1010 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly left truth equational, with witnessing equations $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ in N^b , then $\tau^b \subseteq \dot{L}^{\mathcal{I}}$.*

Proof: Suppose that $\mathcal{I}$ is strongly left truth equational with witnessing equations τ^b . Then, $\mathcal{I}$ is, a fortiori, left truth equational, with the same witnessing equations. It follows, by Lemma 858, that $\tau^b \subseteq L^{\mathcal{I}}$. Since τ^b consists of unary equations and they satisfy the membership criterion for $L^{\mathcal{I}}$, it follows that they also satisfy the condition for membership in $\dot{L}^{\mathcal{I}}$. Therefore, we get that $\tau^b \subseteq \dot{L}^{\mathcal{I}}$. ■

Now we prove the necessity of the left solubility of the unary left Suszko core for strong left truth equationality.

Theorem 1011 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly left truth equational, then $\dot{L}^{\mathcal{I}}$ is left soluble.*

Proof: Suppose that $\mathcal{I}$ is strongly left truth equational, with witnessing equations $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \dot{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{Lemma 1010}) \\ \text{iff} \quad \phi \in \overleftarrow{T}_{\Sigma}. \quad (\text{strong left truth equationality}) \end{aligned}$$

Thus, $\dot{L}^{\mathcal{I}}$ is left soluble. ■

The reverse implication also holds and provides the characterization of strong left truth equationality in terms of the left solubility of the unary left Suszko core.

Theorem 1012 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{L}^{\mathcal{I}}$ is left soluble, then $\mathcal{I}$ is strongly left truth equational, with witnessing equations $\dot{L}^{\mathcal{I}}$.*

Proof: It suffices to show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_{\Sigma} \quad \text{iff} \quad \dot{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 1009, whereas the converse is ensured by the postulated left solubility of $\dot{L}^{\mathcal{I}}$. ■

Theorems 1011 and 1012 provide the promised characterization of strong left truth equationality in terms of the left solubility of the unary left Suszko core.

$$\mathcal{I} \text{ is Strongly Left Truth Equational} \longleftrightarrow \dot{L}^{\mathcal{I}} \text{ is Left Soluble.}$$

Theorem 1013 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly left truth equational if and only if $\dot{L}^{\mathcal{I}}$ is left soluble.*

Proof: Theorem 1011 gives the “only if” and the “if” is by Theorem 1012. ■

If $\mathcal{I}$ is strongly left truth equational, then the unary left Suszko core defines theory families in $\mathcal{I}$, up to arrow, in terms of their Leibniz congruence systems. So, analogously to preceding situations, $\dot{L}^{\mathcal{I}}$ forms a maximal set of witnessing equations of the strong left truth equationality of $\mathcal{I}$.

Proposition 1014 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{L}^{\mathcal{I}}$ is left soluble, then, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} = \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\dot{L}^{\mathcal{I}}$ is left soluble, then, by Theorem 1012, $\dot{L}^{\mathcal{I}}$ forms a set of witnessing equations for the strong left truth equationality of $\mathcal{I}$. Therefore, by Proposition 850, we get that, for every $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T))$. ■

This property provides another characterization of strong left truth equationality. We say that $\dot{L}^{\mathcal{I}}$ **defines theory families up to arrow** if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T))$. Then we have:

$$\begin{aligned} \mathcal{I} \text{ is Strongly Left Truth Equational} \\ \longleftrightarrow \dot{L}^{\mathcal{I}} \text{ Defines Theory Families Up to Arrow.} \end{aligned}$$

Theorem 1015 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly left truth equational if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\overleftarrow{T} = \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is strongly left truth equational, then, by Theorem 1013, $\dot{L}^{\mathcal{I}}$ is left soluble. Thus, by Proposition 1014, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T))$.

Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{\dot{L}^{\mathcal{I}}}(\Omega(T))$, then, $\dot{L}^{\mathcal{I}}$ is left soluble. Thus, again by Theorem 1013, $\dot{L}^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is strongly left truth equational. ■

In analogy with strong truth equationality and family c-reflectivity, the property that separates left complete reflectivity from strong left truth equationality is exactly the left adequacy of the unary left Suszko core. Roughly speaking, this property ensures that the unary left Suszko core is rich enough to define Suszko congruence systems in terms of the Leibniz congruence systems of theory families that it selects via inclusion.

We have the following relationship connecting the unary left Suszko core with both Leibniz and Suszko congruence systems.

Proposition 1016 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^\mathcal{I}(C(\vec{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThFam}(\mathcal{I})$, we have, using Lemma 1007,

$$L_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \quad \text{implies} \quad \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T).$$

Therefore, $\{ \Omega(T) : L_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \subseteq \{ \Omega(T) : \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \}$. We conclude that

$$\bigcap \{ \Omega(T) : \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \leq \bigcap \{ \Omega(T) : L_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^\mathcal{I}(C(\vec{\phi})),$$

where the last inclusion is based on Proposition 864. $\blacksquare$

Again it is possible, but not necessary, that the unary left Suszko core of a π -institution satisfies, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, the reverse inclusion of that given in Proposition 1016:

$$\tilde{\Omega}^\mathcal{I}(C(\vec{\phi})) \leq \bigcap \{ \Omega(T) : \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \}.$$

Intuitively speaking, this means that the unary left Suszko core $\dot{L}^\mathcal{I}$ is rich enough to allow, for every signature Σ and for every Σ -sentence ϕ , the determination of those theory families whose Leibniz congruence systems form a covering of the Suszko congruence system of $C(\vec{\phi})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the unary left Suszko core $\dot{L}^\mathcal{I}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^\mathcal{I}(C(\vec{\phi})) = \bigcap \{ \Omega(T) : \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \}.$$

Based on our preceding work, it is not difficult to see that, if $\dot{L}^\mathcal{I}$ is left soluble, then it is left adequate.

Corollary 1017 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{L}^\mathcal{I}$ is left soluble, then it is left adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \tilde{\Omega}^\mathcal{I}(C(\vec{\phi})) &= \bigcap \{ \Omega(T) : \vec{\phi} \leq T \} \quad (\text{definition of } \tilde{\Omega}^\mathcal{I}(C(\vec{\phi}))) \\ &= \bigcap \{ \Omega(T) : \phi \in \overleftarrow{T}_\Sigma \} \quad (\text{definition of } \overleftarrow{T}) \\ &= \bigcap \{ \Omega(T) : \dot{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \}. \\ &\quad (\text{left solubility of } \dot{L}^\mathcal{I} \text{ and Proposition 1014}) \end{aligned}$$

We conclude that $\dot{L}^\mathcal{I}$ is left adequate. $\blacksquare$

In the opposite direction, in a *left c-reflective* π -institution $\mathcal{I}$, if the unary left Suszko core is left adequate, then it is also left soluble.

Proposition 1018 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a left c-reflective π -institution based on $\mathbf{F}$. If $\dot{L}^{\mathcal{I}}$ is left adequate, then it is left soluble.*

Proof: Suppose that $\mathcal{I}$ is left c-reflective and that $\dot{L}^{\mathcal{I}}$ is left adequate. We must show that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$

$$\phi \in \overleftarrow{T}_{\Sigma} \quad \text{iff} \quad \dot{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 1009. For the converse, assume that $\dot{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by the left adequacy of $\dot{L}^{\mathcal{I}}$, we get that $\tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})) \leq \Omega(T)$. Thus, by left c-reflectivity and Lemma 869, we conclude that $C(\overrightarrow{\phi}) \leq \overleftarrow{T}$. This implies $\phi \in \overleftarrow{T}_{\Sigma}$. ■

We finally show that a π -institution is strongly left truth equational if and only if it is left c-reflective and has a left adequate unary left Suszko core.

$$\begin{aligned} & \text{Strong Left Truth Equationality} \\ &= \dot{L}^{\mathcal{I}} \text{ Left Soluble} \\ &= \dot{L}^{\mathcal{I}} \text{ Defines Theory Families Up to Arrow} \\ &= \text{Left c-Reflectivity} + \dot{L}^{\mathcal{I}} \text{ Left Adequate} \end{aligned}$$

Theorem 1019 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly left truth equational if and only if it is left c-reflective and has a left adequate unary left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly left truth equational. Then, by Theorem 851, it is left c-reflective. Moreover, by Theorem 1013, its unary left Suszko core is left soluble and, hence, by Corollary 1017, its unary left Suszko core is left adequate.

Suppose, conversely, that $\mathcal{I}$ is family c-reflective with a left adequate unary left Suszko core. Then, by Proposition 1018, its unary left Suszko core is left soluble. Hence, by Theorem 1013, $\mathcal{I}$ is strongly left truth equational. ■

We close the section with a result relating the unary left Suszko core with the left Suszko core. More precisely, we show that left adequacy of the unary left Suszko core implies left adequacy of the left Suszko core.

Proposition 1020 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{L}^{\mathcal{I}}$ is left adequate, then $L^{\mathcal{I}}$ is left adequate.*

Proof: Suppose that $\dot{L}^{\mathcal{I}}$ is left adequate. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) &\leq \cap\{\Omega(T) : \dot{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\} \quad (\dot{L}^{\mathcal{I}} \text{ left adequate}) \\ &\leq \cap\{\Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\} \quad (\dot{L}^{\mathcal{I}} \subseteq L^{\mathcal{I}}) \\ &\leq \tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})). \quad (\text{Proposition 864}) \end{aligned}$$

Hence, $\tilde{\Omega}^{\mathcal{I}}(C(\vec{\phi})) = \cap\{\Omega(T) : L_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\}$, and $L^{\mathcal{I}}$ is left adequate. $\blacksquare$

We give an example of a strongly left truth equational π -institution which is not strongly (family) truth equational.

Example 1021 EXAMPLE NOT FOUND YET!!

13.7 Strong System Truth Equationality

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is **strongly system truth equational** if there exists a set $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ in N^b (with a single distinguished argument), such that, for every $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T).$$

In that case, we call τ^b a **set of witnessing equations** (of/for the strong system truth equationality of $\mathcal{I}$).

Again, since τ^b is parameter-free and $\Omega(T)$ is invariant under signature morphisms, strong system truth equationality may be defined equivalently by the condition, for every $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b(\phi) \subseteq \Omega_{\Sigma}(T).$$

We introduce next the unary system core of a π -institution. Analogously with the system core, the unary system core enables one to obtain:

- A characterization of strong system truth equationality in terms of the solubility property of the unary system core of the π -institution.
- An exact description of those system c-reflective π -institutions which are strongly system truth equational.
- A characterization of those system truth equational π -institutions which are strongly system truth equational.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Section 11.10 that, for $T \in \text{ThSys}(\mathcal{I})$, we have introduced the notation

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}(\mathcal{I}) \}.$$

This is a variant of the Suszko operator, allowing one to zoom in on the theory system structure of the π -institution under consideration, which forms naturally the focus in the present section.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **unary system core** of $\mathcal{I}$ is the collection

$$\dot{Z}^{\mathcal{I}} = \{ \sigma^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2 \in N^b : (\forall T \in \text{ThSys}(\mathcal{I})) (\sigma^b[T] \leq \widehat{\Omega}^{\mathcal{I}}(T)) \}.$$

Note that the unary system core of a π -institution is included in the system core, i.e., we have

Lemma 1022 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $\dot{Z}^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$.*

Proof: Every pair of unary natural transformations in N^b that satisfies the membership criterion for $Z^{\mathcal{I}}$ also satisfies the condition for membership in $\dot{Z}^{\mathcal{I}}$. ■

Moreover, we have the following relationship between the sentence families defined via the Leibniz congruence systems by the system and the unary system core.

Corollary 1023 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$, we have*

$$\overleftarrow{Z}^{\mathcal{I}}(\Omega(T)) \leq \overleftarrow{\dot{Z}}^{\mathcal{I}}(\Omega(T)).$$

Proof: By Theorem 107 and Corollary 105. ■

The relation between the unary Suszko core, the unary left Suszko core and the unary system core of a π -institution $\mathcal{I}$ is given in the following proposition, forming an analog of Proposition 876, concerning the general (non-unary) analogs of these sets.

Proposition 1024 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

$$(a) \quad \dot{S}^{\mathcal{I}} \subseteq \dot{L}^{\mathcal{I}} \subseteq \dot{Z}^{\mathcal{I}};$$

$$(b) \quad \text{For every relation family } \theta \text{ on } \mathbf{F}, \quad \overleftarrow{Z}^{\mathcal{I}}(\theta) \leq \overleftarrow{\dot{L}}^{\mathcal{I}}(\theta) \leq \overleftarrow{\dot{S}}^{\mathcal{I}}(\theta).$$

Proof: From Proposition 876, we have that $S^{\mathcal{I}} \subseteq L^{\mathcal{I}} \subseteq Z^{\mathcal{I}}$. Thus, Part (a) follows by applying the $\dot{}$ operator (which is monotone) to this chain of inclusions. Part (b) follows from Part (a) and the relevant definitions. ■

Either directly by the definition or using Proposition 877 together with Corollary 1023, we get the following

Proposition 1025 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $T \in \text{ThSys}(\mathcal{I})$,*

$$T \leq \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T)).$$

Proof: We have $T \leq \overleftarrow{Z^{\mathcal{I}}}(\Omega(T)) \leq \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T))$, where the first inclusion is by Lemma 877 and the second by Corollary 1023. ■

The unary system core of a π -institution may or may not satisfy the reverse inclusion of Proposition 1025, a property that was called previously, in similar contexts, *solubility*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the unary system core of $\mathcal{I}$ is **soluble** if, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T)) \leq T.$$

Note that $\dot{Z}^{\mathcal{I}}$ is soluble if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\dot{Z}_{\Sigma}^{\mathcal{I}}(\phi) \subseteq \Omega_{\Sigma}(T) \quad \text{implies} \quad \phi \in T_{\Sigma}.$$

It turns out that possession of the solubility property by the unary system core intrinsically characterizes strong system truth equationality. To show the necessity of solubility, we observe, once again, that, in case a π -institution is strongly system truth equational, the witnessing equations form a subset of the unary system core.

Lemma 1026 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly system truth equational, with witnessing equations $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2 \subseteq N^b$, then $\tau^b \subseteq \dot{Z}^{\mathcal{I}}$.*

Proof: Suppose that $\mathcal{I}$ is strongly system truth equational with witnessing equations τ^b . Then, $\mathcal{I}$ is, a fortiori, system truth equational, with the same witnessing equations. It follows, by Lemma 879, that $\tau^b \subseteq Z^{\mathcal{I}}$. Since τ^b consists of unary equations and they satisfy the membership criterion for $Z^{\mathcal{I}}$, it follows that they also satisfy the condition for membership in $\dot{Z}^{\mathcal{I}}$. Therefore, we get that $\tau^b \subseteq \dot{Z}^{\mathcal{I}}$. ■

Now we prove the necessity of the solubility of the unary system core for strong system truth equationality.

Theorem 1027 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly system truth equational, then $\dot{Z}^{\mathcal{I}}$ is soluble.*

Proof: Suppose that $\mathcal{I}$ is strongly system truth equational, with witnessing equations $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$. Then, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) & \text{ implies } \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{Lemma 1026}) \\ \text{iff } \phi \in T_{\Sigma}, & \end{aligned}$$

where the last equivalence is based on the postulated strong system truth equationality of $\mathcal{I}$. Thus, $\dot{Z}^{\mathcal{I}}$ is soluble. ■

The reverse implication completes the promised characterization of strong system truth equationality in terms of the solubility of the unary system core.

Theorem 1028 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is soluble, then $\mathcal{I}$ is strongly system truth equational, with witnessing equations $\dot{Z}^{\mathcal{I}}$.*

Proof: It suffices to show that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The left-to-right implication is given in Proposition 1025, whereas the converse is ensured by the postulated solubility of $\dot{Z}^{\mathcal{I}}$. ■

Theorems 1027 and 1028 provide the promised characterization of strong system truth equationality in terms of the solubility of the unary system core.

$$\mathcal{I} \text{ is Strongly System Truth Equational} \longleftrightarrow \dot{Z}^{\mathcal{I}} \text{ is Soluble.}$$

Theorem 1029 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly system truth equational if and only if $\dot{Z}^{\mathcal{I}}$ is soluble.*

Proof: Theorem 1027 gives the “only if” and the “if” is by Theorem 1028. ■

If $\mathcal{I}$ is strongly system truth equational, then the unary system core defines theory systems in $\mathcal{I}$ in terms of their Leibniz congruence systems. This proposition may be viewed as a special case of Proposition 873, since $\dot{Z}^{\mathcal{I}}$ forms a maximal set of witnessing equations of the strong system truth equationality of $\mathcal{I}$.

Proposition 1030 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is soluble, then, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$T = \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\dot{Z}^{\mathcal{I}}$ is soluble, then, by Theorem 1028, $\dot{Z}^{\mathcal{I}}$ forms a set of witnessing equations for the strong system truth equationality of $\mathcal{I}$. Therefore, by Proposition 873, we get that, for every $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T))$. ■

This property provides another characterization of strong system truth equationality. We say that $\dot{Z}^{\mathcal{I}}$ **defines theory systems** if, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T))$. Then we have:

$$\mathcal{I} \text{ is Strongly System Truth Equational} \\ \longleftrightarrow \dot{Z}^{\mathcal{I}} \text{ Defines Theory Systems.}$$

Theorem 1031 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly system truth equational if and only if, for all $T \in \text{ThSys}(\mathcal{I})$,*

$$T = \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T)).$$

Proof: If $\mathcal{I}$ is strongly system truth equational, then, by Theorem 1029, $\dot{Z}^{\mathcal{I}}$ is soluble. Thus, by Proposition 1030, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T))$.

Conversely, if, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \overleftarrow{\dot{Z}^{\mathcal{I}}}(\Omega(T))$, then, $\dot{Z}^{\mathcal{I}}$ is soluble. Thus, again by Theorem 1029, $\dot{Z}^{\mathcal{I}}$ is a set of witnessing equations and $\mathcal{I}$ is strongly system truth equational. ■

It turns out that the property that separates system complete reflectivity from strong system truth equationality is exactly the adequacy property of the unary system core. Roughly speaking, this property ensures that the unary system core is rich enough to define the congruence system $\widehat{\Omega}^{\mathcal{I}}(T)$ of a theory system T in terms of the Leibniz congruence systems of theory systems that it selects via inclusion.

Proposition 1032 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThSys}(\mathcal{I})$, we have, using Lemma 1022,

$$Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

Therefore,

$$\begin{aligned} & \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ & \subseteq \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \end{aligned}$$

We conclude that

$$\begin{aligned} & \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ & \leq \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})), \end{aligned}$$

where the last inclusion is based on Proposition 885. ■

It is possible, but not necessary, that the unary system core of a π -institution satisfies, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, the reverse inclusion of that given in Proposition 1032:

$$\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) \leq \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Intuitively speaking, this means that the unary system core $\dot{Z}^{\mathcal{I}}$ is rich enough to allow, for every signature Σ and every Σ -sentence ϕ , the determination of those theory systems whose Leibniz congruence systems form a covering of $\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi}))$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the unary system core $\dot{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) = \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Based on our preceding work, it is not difficult to see that, if $\dot{Z}^{\mathcal{I}}$ is soluble, then it is adequate.

Corollary 1033 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) &= \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in T_{\Sigma} \} \\ &\quad (\text{definition of } \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi}))) \\ &= \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \\ &\quad (\text{solubility of } \dot{Z}^{\mathcal{I}} \text{ and Proposition 1030}) \end{aligned}$$

We conclude that $\dot{Z}^{\mathcal{I}}$ is adequate. ■

In the opposite direction, in a system *c-reflective* π -institution $\mathcal{I}$, if the unary system core is adequate, then it is also soluble.

Proposition 1034 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a system *c-reflective* π -institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose that $\mathcal{I}$ is system c-reflective and that $\dot{Z}^{\mathcal{I}}$ is adequate. We must show that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

The implication left-to-right is always satisfied by Proposition 1025. For the converse, assume that $\dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by the adequacy of $\dot{Z}^{\mathcal{I}}$, we get that $\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) \leq \Omega(T)$. Thus, by system c-reflectivity and Lemma 887, we conclude that $C(\vec{\phi}) \leq T$, which gives $\phi \in T_{\Sigma}$. ■

We finally show that a π -institution is strongly system truth equational if and only if it is system c-reflective and has an adequate unary system core.

$$\begin{aligned} \text{Strong System Truth Equationality} \\ &= \dot{Z}^{\mathcal{I}} \text{ Soluble} \\ &= \dot{Z}^{\mathcal{I}} \text{ Defines Theory Systems} \\ &= \text{System c-Reflectivity} + \dot{Z}^{\mathcal{I}} \text{ Adequate} \end{aligned}$$

Theorem 1035 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is strongly system truth equational if and only if it is system c-reflective and has an adequate unary system core.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly system truth equational. Then, by Theorem 874, it is system c-reflective. Moreover, by Theorem 1029, its unary system core is soluble and, hence, by Corollary 1033, its unary system core is adequate.

Suppose, conversely, that $\mathcal{I}$ is system c-reflective with an adequate unary system core. Then, by Proposition 1034, its unary system core is soluble and, therefore, by Theorem 1029, $\mathcal{I}$ is strongly system truth equational. ■

We close the section with a result relating the unary system core with the system core. More precisely, we show that adequacy of the unary system core implies adequacy of the system core.

Proposition 1036 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\dot{Z}^{\mathcal{I}}$ is adequate, then $Z^{\mathcal{I}}$ is adequate.*

Proof: Suppose that $\dot{Z}^{\mathcal{I}}$ is adequate. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) &\leq \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \dot{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ &\quad (\dot{Z}^{\mathcal{I}} \text{ adequate}) \\ &\leq \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ &\quad (\dot{Z}^{\mathcal{I}} \subseteq Z^{\mathcal{I}}) \\ &\leq \widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})). \quad (\text{Proposition 885}) \end{aligned}$$

Hence, $\widehat{\Omega}^{\mathcal{I}}(C(\vec{\phi})) = \cap\{\Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } Z_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)\}$, and $Z^{\mathcal{I}}$ is adequate. ■

We give an example of a strongly system truth equational π -institution which is not strongly left truth equational.

Example 1037 EXAMPLE NOT FOUND YET!!

13.8 Syntactic Left PreAlgebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution. Recall from Chapter 5 that $\mathcal{I}$ belongs to one of the classes of the *prealgebraizability hierarchy* when its Leibniz operator is monotone on theory systems and it has a certain kind of extensionality and a certain kind of injectivity or reflectivity or complete reflectivity property. We now turn to corresponding properties defined via “syntactic” means. Keeping a level of consistency, we will call *syntactically prealgebraizable* any π -institution whose Leibniz operator on theory systems is definable via a set of binary natural transformations in N^b , i.e., a parameter free set of natural transformations in N^b , and, additionally, has a certain kind of definability property of truth, via a, possibly, parameter free set of equations in N^b . If the situation is reversed and definability of truth is required to be via a parameter free set of equations, but that is not demanded of the definability of Leibniz congruence systems, then we obtain the classes of *anti-prealgebraizable* π -institutions, a term concocted here to convey a kind of chiral symmetry in applying “parameterlessness”. The hierarchy we aim for consists of the six classes depicted in the following diagram.

Membership in the classes of the central column imposes parameter free definability of both the Leibniz operator on theory systems and a kind of parameter free definability of truth. Membership in the classes in the left column insists only on parameter free definability of the Leibniz operator, whereas, symmetrically, membership in the classes of the right column postulates only a kind of parameter free definability of truth.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. In agreement with preestablished nomenclature, we say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -**fortified** if it has:

- A locally Leibniz binary reflexive core;
- A left adequate unary left Suszko core.

We say that $\mathcal{I}$ is **syntactically strongly left prealgebraizable** if it is

- $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified;
- preequivalential (i.e., prealgebraic and system extensional);
- left c-reflective.

Our preceding work in this chapter has paved the way for the following important characterization of syntactic strong left prealgebraizability.

Theorem 1038 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is syntactically preequivalential and strongly left truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by definition, it is

- preequivalential and has a locally Leibniz binary reflexive core;
- left c-reflective and has a left adequate unary left Suszko core;

if and only if, by Theorems 974 and 1019, it is syntactically preequivalential and strongly left truth equational. ■

An alternative characterization along similar lines relates the syntactic with the corresponding semantic notions introduced in the context of prealgebraizability in Chapter 5.

Theorem 1039 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by definition,

- it is preequivalential and left c-reflective;
- it has a locally Leibniz binary reflexive core and a left adequate unary left Suszko core;

if and only if, by definition, it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified. ■

This characterization in terms of semantic properties and preceding work on transference of properties from theory families/systems to filter families/systems on arbitrary algebraic systems yield yet another characterization of syntactic strong left prealgebraizability, which may also be viewed as a kind of transfer property for this class in its own right.

Theorem 1040 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and left c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by Theorem 1039, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and LC prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and left c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and congruence systems, we have the following result.

Theorem 1041 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding

$$\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

that commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if, by Theorem 1039, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and LC prealgebraizable if and only if, by Theorem 355, it is $\ddot{R}^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ that commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 952.

Theorem 1042 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}^\bullet}$ of natural transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is strongly left truth equational and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair of natural transformations. Then it is strongly left truth equational and, by Theorem 944, it is syntactically preequivalential. Thus, by Theorem 1038, it is syntactically strongly left prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly left prealgebraizable. Then, by Theorem 1038, it is strongly left truth equational and syntactically preequivalential. Hence, by Theorem 937, it is syntactically WS prealgebraizable. Now it follows by Theorem 943 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a pair $(\tau^b, \overset{\leftrightarrow}{I}^b)$, where I^b witnesses the syntactic preequivalentiality and τ^b the syntactic strong left truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ■

Again, the equivalence of the systemic skeleton with an equational π -structure via a conjugate pair of natural transformations, coupled with strong left truth equationality, is sufficient to ensure syntactic strong left prealgebraizability.

Theorem 1043 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly left prealgebraizable, then, by Theorem 1042, it is strongly left truth equational and its systemic skeleton is equivalent to an algebraic π -structure via a conjugate pair of natural transformations. Suppose, conversely, that $\mathcal{I}$ is strongly left truth equational and its systemic skeleton is equivalent to an algebraic π -structure via a conjugate pair of natural transformations. Then, it is strongly left truth equational and, by Proposition 930, it is syntactically preequivalential. Therefore, by Theorem 1038, it is syntactically strongly left prealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically strongly left prealgebraizable π -institutions.

Theorem 1044 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly left prealgebraizable if and only if it is strongly left truth equational and there exists*

a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of natural transformations, where $\mathcal{Q}$ is an equational π -structure.

Proof: The “only if” follows by Theorem 1043 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1043. ■

Flanking the class of syntactically strongly left prealgebraizable π -institutions are the classes of *syntactically left prealgebraizable* and *syntactically left antiprealgebraizable* π -institutions. These two classes are now defined formally.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -**fortified** if it has:

- A locally Leibniz binary reflexive core;
- A left adequate left Suszko core.

The π -institution $\mathcal{I}$ is **syntactically left prealgebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is preequivalential;
- $\mathcal{I}$ is left c-reflective.

We say that $\mathcal{I}$ is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -**fortified** if it has:

- A Leibniz reflexive core;
- A left adequate unary left Suszko core.

The π -institution $\mathcal{I}$ is **syntactically left antiprealgebraizable** if:

- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is prealgebraic;
- $\mathcal{I}$ is left c-reflective.

For both of these classes we have analogs of many of the results proven above for syntactic strong left prealgebraizability. Before formulating them, let us observe that:

- Preequivalentiality is stronger than prealgebraicity (Definition 329);
- Under prealgebraicity, $\ddot{R}^{\mathcal{I}}$ locally Leibniz implies $R^{\mathcal{I}}$ Leibniz ($\ddot{R}^{\mathcal{I}} \subseteq R^{\mathcal{I}}$ and monotonicity of Ω on theory systems);
- $\dot{L}^{\mathcal{I}}$ left adequate implies $L^{\mathcal{I}}$ left adequate (Proposition 1020).

So we get, immediately from the definitions, the following hierarchical relations between the upper three classes in the echelon formation of the preceding diagram.

We now provide examples to show that the two inclusions are proper. We do this by demonstrating that the two bottom classes are incomparable. So, for the first arrow, we provide an example of a π -institution which is syntactically left prealgebraizable but not syntactically left antiprealgebraizable.

Example 1045 EXAMPLE NOT FOUND YET!!

For the second arrow, we give an example of a syntactically left antiprealgebraizable π -institution which fails to be syntactically left prealgebraizable.

Example 1046 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1038 relates these two chiral types of syntactic left prealgebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1047 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is syntactically preequivalential and left truth equational.*
- (b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is syntactically prealgebraic and strongly left truth equational.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by definition, it is preequivalential, with a locally Leibniz binary reflexive core, and left c-reflective, with a left adequate left Suszko core, if and only if, by Theorems 974 and 871, is it syntactically preequivalential and left truth equational.
- (b) Similarly, $\mathcal{I}$ is syntactically left antiprealgebraizable if and only if, by definition, it is prealgebraic, with a Leibniz reflexive core, and left c-reflective, with a left adequate unary left Suszko core, if and only if, by Theorems 788 and 1019, is it syntactically prealgebraic and strongly left truth equational.

■

An alternative characterization, analogous to that of Theorem 1039, relates the syntactic with the corresponding semantic notions.

Theorem 1048 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified.*
- (b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is weakly LC prealgebraizable and $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by definition, it is preequivalential and left c-reflective and, moreover, it has a locally Leibniz binary reflexive core and a left adequate left Suszko core. This happens if and only if, by definition, it is LC prealgebraizable and $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified.
- (b) Similarly, $\mathcal{I}$ is syntactically left antiprealgebraizable if and only if, by definition, it is prealgebraic and left c-reflective and, moreover, it has a Leibniz reflexive core and a left adequate unary left Suszko core. This happens if and only if, by definition, it is weakly LC prealgebraizable and $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified.

■

This characterization in terms of semantic properties and preceding work on transference of properties from theory families/systems to filter families/systems on arbitrary algebraic systems yield a kind of transfer property for syntactic left (anti)prealgebraizability.

Theorem 1049 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and left c-reflective.*
- (b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems and left c-reflective.*

Proof: We prove only Part (a), since Part (b) is similar. We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by Theorem 1048, it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and LC prealgebraizable if and only if, by Theorem 349, it

is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and left c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result.

Theorem 1050 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ that commutes with inverse logical extensions.

- (b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is $R^{\mathcal{I}}\dot{L}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$.

Proof: Again we show only Part (a). Part (b) is similar. We have that $\mathcal{I}$ is syntactically left prealgebraizable if and only if, by Theorem 1048, it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and LC prealgebraizable if and only if, by Theorem 355, it is $\ddot{R}^{\mathcal{I}}L^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is a left completely order reflecting surjection that restricts to an order embedding $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ that commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 1042.

Theorem 1051 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is left truth equational and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations, with I^b natural.*
- (b) *$\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is strongly left truth equational and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations, with τ^b natural.*

Proof:

- (a) Suppose, first, that $\mathcal{I}$ is left truth equational and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then it is left truth equational and, by Theorem 944, it is syntactically preequivalent. Thus, by Theorem 1047, it is syntactically left prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically left prealgebraizable. Then, by Theorem 1047, it is left truth equational and syntactically preequivalent. Hence, by Theorem 937, it is syntactically WS prealgebraizable. Now it follows by Theorem 943 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^b, \overset{\leftrightarrow}{I}^b)$, where I^b witnesses the syntactic preequivalentiality and τ^b the left truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with I^b natural.

- (b) Suppose, first, that $\mathcal{I}$ is strongly left truth equational and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then it is strongly left truth equational and, by Theorem 944, it is syntactically prealgebraic. Thus, by Theorem 1047, it is syntactically left antiprealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically left antiprealgebraizable. Then, by Theorem 1047, it is strongly left truth equational and syntactically prealgebraic. Hence, by Theorem 937, it is syntactically WS prealgebraizable. Now it follows by Theorem 943 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^b, \overset{\leftrightarrow}{I}^b)$, where I^b witnesses the syntactic prealgebraicity and τ^b the strong left truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with τ^b natural.

■

The equivalence of the systemic skeleton with an equational π -structure via a conjugate pair of transformations, exhibiting the required one-sided naturality condition, coupled with either left truth equationality or strong left truth equationality, depending on the case considered, is sufficient to ensure syntactic left (anti)prealgebraizability.

Theorem 1052 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically left prealgebraizable if and only if it is left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural.*

- (b) $\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is strongly left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural.

Proof:

- (a) If $\mathcal{I}$ is syntactically left prealgebraizable, then, by Theorem 1051, it is left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Suppose, conversely, that $\mathcal{I}$ is left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, it is left truth equational and, by Proposition 930, it is syntactically preequivalent. Therefore, by Theorem 1047, it is syntactically left prealgebraizable.
- (b) If $\mathcal{I}$ is syntactically left antiprealgebraizable, then, by Theorem 1051, it is strongly left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Suppose, conversely, that $\mathcal{I}$ is strongly left truth equational and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, it is strongly left truth equational and, by Proposition 930, it is syntactically prealgebraic. Therefore, by Theorem 1047, it is syntactically left antiprealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically left (anti)prealgebraizable π -institutions.

Theorem 1053 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) $\mathcal{I}$ is syntactically left prealgebraizable if and only if it is left truth equational and there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an equational π -structure and I^b is natural.
- (b) $\mathcal{I}$ is syntactically left antiprealgebraizable if and only if it is strongly left truth equational and there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an equational π -structure and τ^b is natural.

Proof: The “only if” follows by Theorem 1052 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1052. ■

In this section we have introduced the three syntactic left prealgebraizability classes

In the next section, we shall introduce, following a similar path, the remaining three syntactic prealgebraizability classes, namely those of the system prealgebraizable π -institutions, in order to complete the syntactic prealgebraizability hierarchy that was described at the beginning of the section.

13.9 Syntactic System PreAlgebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified if:

- $\mathcal{I}$ has a locally Leibniz binary reflexive core;
- $\mathcal{I}$ has an adequate unary system core.

We say that $\mathcal{I}$ is **syntactically strongly system prealgebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is preequivalential (i.e., prealgebraic and system extensional);
- $\mathcal{I}$ is system c-reflective.

An analog of Theorem 1038 provides an important characterization of syntactic strong system prealgebraizability in terms of lower classes in the syntactic hierarchy.

Theorem 1054 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is syntactically preequivalential and strongly system truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by definition, it is

- preequivalential and has a locally Leibniz binary reflexive core;

- system c-reflective and has an adequate unary system core;

if and only if, by Theorems 974 and 1035, is it syntactically preequivalential and strongly system truth equational. ■

An analog of Theorem 1039 gives an alternative characterization of the syntactic notion in terms of the corresponding semantic notions.

Theorem 1055 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is system prealgebraizable and $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by definition,

- it is preequivalential and system c-reflective;
- it has a locally Leibniz binary reflexive core and an adequate unary system core;

if and only if, by definition, it is system prealgebraizable and, also, $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. ■

This characterization in terms of semantic properties and preceding work on transference of properties from theory systems to filter systems on arbitrary algebraic systems yield yet another characterization of syntactic strong system prealgebraizability analogous to that of Theorem 1040, which may also be viewed as a kind of transfer property on its own right.

Theorem 1056 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on theory systems, system extensional and system c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by Theorem 1055, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and system prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and system c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result:

Theorem 1057 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding which commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if, by Theorem 1055, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and system prealgebraizable if and only if, by Theorem 353, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order embedding which commutes with inverse logical extensions. ■

Finally, in an analog of Theorem 1042, using conjugate pairs of transformations, we get

Theorem 1058 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of natural transformations.*

Proof: Suppose, first, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair of natural transformations. Then, by Theorem 945, it is strongly system truth equational and, by Theorem 944, it is syntactically preequivalential. Thus, by Theorem 1054, it is syntactically strongly system prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly system prealgebraizable. Then, by Theorem 1054, it is strongly system truth equational and syntactically preequivalential. Hence, by Theorem 937, it is syntactically WS prealgebraizable. Now it follows by Theorem 943 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a pair $(\tau^b, \overset{\leftrightarrow}{I}^b)$, where I^b witnesses the syntactic preequivalentiality and τ^b the syntactic strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ■

Analogously with Theorem 1043, the equivalence of the systemic skeleton with some equational π -structure via a conjugate pair of natural transformations suffices to ensure syntactic strong system prealgebraizability.

Theorem 1059 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly system prealgebraizable, then, by Theorem 1058, its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of natural transformations. Suppose, conversely, that the systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair of natural transformations. Then, by Proposition 930, it is syntactically preequivalential and, by Theorem 945, it is strongly system truth equational. Therefore, by Theorem 1054, it is syntactically strongly system prealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1044, providing an alternative characterization of syntactically strongly system prealgebraizable π -institutions.

Theorem 1060 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly system prealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of natural transformations, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 1059 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1059. ■

In the case of syntactic strong left prealgebraizability, studied in the preceding section, below that class sat two wider classes obtained by weakening the naturality requirement either on the side of the witnesses of prealgebraicity or on the side of the witnesses of truth equationality. Similarly here, we get below the class of syntactically strongly system prealgebraizable π -institutions the classes of *syntactically system prealgebraizable* and *syntactically system antiprealgebraizable* π -institutions. These two classes are now defined formally.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified if:

- $\mathcal{I}$ has a locally Leibniz binary reflexive core;
- $\mathcal{I}$ has an adequate system core.

We say that $\mathcal{I}$ is **syntactically system prealgebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is preequivalential;
- $\mathcal{I}$ is system c-reflective.

Further, we say that $\mathcal{I}$ is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified if:

- $\mathcal{I}$ has a Leibniz reflexive core;
- $\mathcal{I}$ has an adequate unary system core.

We say that $\mathcal{I}$ is **syntactically system antiprealgebraizable** if:

- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is prealgebraic;
- $\mathcal{I}$ is system c-reflective.

For both of these classes we have analogs of many of the results proven above for syntactic strong system prealgebraizability. Recall, once more, that:

- Preequivalentiality is stronger than prealgebraicity.
- Under prealgebraicity, $\ddot{R}^{\mathcal{I}}$ locally Leibniz implies $R^{\mathcal{I}}$ Leibniz.
- $\dot{Z}^{\mathcal{I}}$ adequate implies $Z^{\mathcal{I}}$ adequate.

So we get, immediately from the definitions, the following hierarchical relations between the three classes involving syntactic system prealgebraizability.

We provide examples to show that the inclusions shown are proper. The first is an example of a π -institution which is syntactically system prealgebraizable but not syntactically system antiprealgebraizable.

Example 1061 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically system antiprealgebraizable π -institution which fails to be syntactically system prealgebraizable.

Example 1062 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1047 relates these two chiral types of syntactic system prealgebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1063 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- $\mathcal{I}$ is syntactically system prealgebraizable if and only if it is syntactically preequivalential and system truth equational.*
- $\mathcal{I}$ is syntactically system antiprealgebraizable if and only if it is syntactically prealgebraic and strongly system truth equational.*

Proof:

- We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by definition, it is preequivalential, with a locally Leibniz binary reflexive core, and system c-reflective, with an adequate system core, if and only if, by Theorems 974 and 889, is it syntactically preequivalential and system truth equational.

- (b) We have that $\mathcal{I}$ is syntactically system antiprealgebraizable if and only if, by definition, it is prealgebraic, with a Leibniz reflexive core, and system c-reflective, with an adequate unary system core, if and only if, by Theorems 788 and 1035, is it syntactically prealgebraic and strongly system truth equational. ■

An alternative characterization, analogous to that of Theorem 1048, relates the syntactic with the corresponding semantic notions.

Theorem 1064 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if it is system prealgebraizable and $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified.*
- (b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if it is weakly system prealgebraizable and $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by definition, it is preequivalential and system c-reflective and, moreover, it has a locally Leibniz binary reflexive core and an adequate system core. This happens if and only if, by definition, it is system prealgebraizable and $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified.
- (b) Similarly, $\mathcal{I}$ is syntactically system antiprealgebraizable if and only if, by definition, it is prealgebraic and system c-reflective and, moreover, it has a Leibniz reflexive core and an adequate unary system core. This happens if and only if, by definition, it is weakly system prealgebraizable and $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. ■

As far as transferring the properties defining syntactic system (anti)prealgebraizability from theory systems to filter systems on arbitrary algebraic systems, we get the following transfer theorem.

Theorem 1065 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and system c-reflective.*
- (b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems and system c-reflective.*

Proof: We prove only Part (a). The proof of Part (b) follows along similar lines. We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by Theorem 1064, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and system prealgebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter systems, system extensional and system c-reflective. ■

As far as characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following analog of Theorem 1050.

Theorem 1066 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding which commutes with inverse logical extensions.

- (b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order embedding.

Proof: Again we show only Part (a), since Part (b) follows similar reasoning. We have that $\mathcal{I}$ is syntactically system prealgebraizable if and only if, by Theorem 1064, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and system prealgebraizable if and only if, by Theorem 353, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathbf{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order embedding which commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 1051.

Theorem 1067 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations, with I^b natural.*
- (b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}\bullet}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}\bullet}$ of transformations, with τ^b natural.*

Proof:

- (a) Suppose, first, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, by Theorem 944, it is syntactically preequivalential and, by Theorem 945, it is system truth equational. Thus, by Theorem 1063, it is syntactically system prealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically system prealgebraizable. Then, by Theorem 1063, it is syntactically preequivalential and system truth equational. Hence, by Theorem 937, it is syntactically WS prealgebraizable. Now it follows by Theorem 943 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a pair $(\tau^b, \vec{I}^b)$, where I^b witnesses the syntactic preequivalentiality and τ^b the system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with I^b natural.

- (b) Suppose, first, $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, by Theorem 944, it is syntactically prealgebraic and, by Theorem 945, it is strongly system truth equational. Thus, by Theorem 1063, it is syntactically system antiprealgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically system antiprealgebraizable. Then, by Theorem 1063, it is syntactically prealgebraic and strongly system truth equational. Hence, by Theorem 937, it is syntactically WS prealgebraizable. Now it follows by Theorem 943 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^\bullet}$ via a pair $(\tau^b, \vec{I}^b)$, where I^b witnesses the syntactic prealgebraicity and τ^b the strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with τ^b natural. ■

The equivalence of the systemic skeleton with some equational π -structure via a conjugate pair of transformations, exhibiting the required one-sided naturality condition, is sufficient to ensure syntactic system (anti)prealgebraizability. This constitutes an analog of Theorem 1052.

Theorem 1068 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural.*
- (b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural.*

Proof:

- (a) If $\mathcal{I}$ is syntactically system prealgebraizable, then, by Theorem 1067, its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations with I^b natural. Suppose, conversely, that the systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, by Proposition 930, it is syntactically preequational and, by Theorem 945, it is system truth equational. Therefore, by Theorem 1063, it is syntactically system prealgebraizable.
- (b) If $\mathcal{I}$ is syntactically system antiprealgebraizable, then, by Theorem 1067, its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Suppose, conversely, that $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, by Proposition 930, it is syntactically prealgebraic and, by Theorem 945, it is strongly system truth equational. Therefore, by Theorem 1063, it is syntactically system antiprealgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1053, giving an alternative characterization of syntactically system (anti)prealgebraizable π -institutions:

Theorem 1069 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically system prealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an equational π -structure and I^b is natural.*
- (b) *$\mathcal{I}$ is syntactically system antiprealgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an equational π -structure and τ^b is natural.*

Proof: The “only if” follows by Theorem 1068 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1068. ■

Finally, since we have now described in detail the six classes of the syntactic prealgebraizability hierarchy, it is only appropriate to pause and look for examples that separate the left prealgebraizability from the system prealgebraizability classes, i.e., examples showing that the vertical arrows in the

following 6-class diagram

represent, in fact, proper inclusions. We can do this in one swoop by exhibiting an example of a syntactically strong system prealgebraizable π -institution which is neither syntactically left prealgebraizable nor syntactically left antiprealgebraizable.

Example 1070 EXAMPLE NOT FOUND YET!

13.10 Syntactic Family Algebraizability

We now preview the full hierarchy of syntactically prealgebraizable π -institutions that will be established in Sections 13.10 and 13.11. The bottom six classes are the ones established in Sections 13.8 and 13.9, where prealgebraizability refers to the fact that monotonicity is only applied to theory systems. The top six classes concern syntactic algebraizability, where monotonicity is applied to all theory families. The bottom row of this upper tier consists of those π -institutions, where c-reflectivity is postulated only for theory systems. The very top row above it refers to applying left c-reflectivity to theory families. In the second from top class, system (or, equivalently, left c-reflectivity) is postulated in conjunction with family monotonicity and at the very top row family c-reflectivity is combined with family monotonicity. Finally, as far as columns go, they incorporate meanings similar to the ones described for the cohorts of classes introduced in the preceding sections. The left column applies parameter freeness only to the natural transformations witnessing syntactic protoalgebraicity. The right column insists on parameter freeness for the witnessing equations for the truth equationality of the π -institution, whereas the middle column is combining those properties and consists of those classes of π -institutions that are syntactically protoalgebraic and syntactically truth equational, with both properties having parameter free witnessing transformations and witnessing equations, respectively. The complete picture that emerges at the end of Sections 13.10 and 13.11, after adding to the six-class diagram concluding Section 13.9 six more classes, is shown in the accompanying diagram.

We start by defining the class at the apex of the diagram. Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified if:

- $\mathcal{I}$ has a locally Leibniz binary reflexive core;
- $\mathcal{I}$ has an adequate unary Suszko core.

We say that $\mathcal{I}$ is **syntactically strongly family algebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is equivalential (i.e., protoalgebraic and family extensional);
- $\mathcal{I}$ is family c-reflective.

Based on previous work, we can formulate the following important characterization of syntactic strong family algebraizability.

Theorem 1071 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is syntactically equivalential and strongly truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by definition, it is

- equivalential and has a locally Leibniz binary reflexive core;
- family c-reflective and has an adequate unary Suszko core;

if and only if, by Theorems 989 and 1003, is it syntactically preequivalential and strongly left truth equational. ■

An alternative characterization along similar lines relates the syntactic with the corresponding semantic notions introduced in the context of algebraizability.

Theorem 1072 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is family algebraizable and $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by definition,

- it is equivalential and family c-reflective;
- it has a locally Leibniz binary reflexive core and an adequate unary Suszko core;

if and only if, by definition, it is family algebraizable (recall that family injectivity and family c-reflectivity coincide under protoalgebraicity) and $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified. ■

This characterization in terms of semantic properties and preceding work on transference of properties from theory families to filter families on arbitrary algebraic systems yields another characterization of syntactic strong family algebraizability, which may also be viewed as a kind of transfer property in its own right.

Theorem 1073 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and family c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by Theorem 1072, it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and family algebraizable if and only if, by Theorem 364, it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone and injective (equivalently c-reflective) on $\mathcal{I}$ -filter families and family extensional. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result.

Theorem 1074 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly family algebraizable if and only if, by Theorem 1072, it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and family algebraizable if and only if, by Theorem 366 it is $\ddot{R}^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. ■

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 952.

Theorem 1075 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is equivalent to its associated algebraic π -structure $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ of natural transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair of natural transformations. Then it is syntactically equivalential by Corollary 975 and it is family truth equational by Theorem 913. Thus, by Theorem 1071, it is syntactically strongly family algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly family algebraizable. Then, by Theorem 1071, it is strongly family truth equational and syntactically equivalential. Hence, by Theorem 915, it is syntactically WF algebraizable. Now it follows by Theorem 921 that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a pair $(\tau^b, \vec{I}^b)$, where I^b witnesses the syntactic equivalentiality and τ^b the syntactic strong truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ■

It turns out, in this case also, that the equivalence of the π -institution with an equational π -structure via a conjugate pair of natural transformations is sufficient to ensure syntactic strong family algebraizability.

Theorem 1076 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if it is equivalent to an equational π -structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly family algebraizable, then, by Theorem 1075, it is equivalent to an equational π -structure via a conjugate pair of natural transformations. Suppose, conversely, that $\mathcal{I}$ is equivalent to an

equational π -structure via a conjugate pair of natural transformations. Then, it is syntactically equivalential by Corollary 975 and it is strongly family truth equational by Theorem 913. Therefore, by Theorem 1071, it is syntactically strongly family algebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactically strongly family algebraizable π -institutions.

Theorem 1077 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly family algebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of natural transformations, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 1076 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1076. ■

Lying just underneath the class of syntactically strongly family algebraizable π -institutions are the classes of *syntactically family algebraizable* and *syntactically family antialgebraizable* π -institutions. Similarly to the scenarios examined in Sections 13.8 and 13.9, these two classes are obtained by weakening the parameterlessness requirement on one of the two sides.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **$\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified** if:

- $\mathcal{I}$ has a locally Leibniz binary reflexive core;
- $\mathcal{I}$ has an adequate Suszko core.

$\mathcal{I}$ is **syntactically family algebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is equivalential;
- $\mathcal{I}$ is family c-reflective.

Similarly, we say that $\mathcal{I}$ is **$R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified** if:

- $\mathcal{I}$ has a Leibniz reflexive core;
- $\mathcal{I}$ has an adequate unary Suszko core.

$\mathcal{I}$ is **syntactically family antialgebraizable** if:

- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is protoalgebraic;

- $\mathcal{I}$ is family c-reflective.

We formulate analogs of many of the results proven previously for the various kinds of syntactic prealgebraizability properties. Observe, first, that:

- Equivalentiality is stronger than protoalgebraicity.
- Under prealgebraicity, $\ddot{R}^{\mathcal{I}}$ locally Leibniz implies $R^{\mathcal{I}}$ Leibniz.
- $\dot{S}^{\mathcal{I}}$ adequate implies $S^{\mathcal{I}}$ adequate.

So we get immediately from the definitions the following hierarchical relations between the three topmost classes in the syntactic algebraizability hierarchy.

We now provide examples to show that the two inclusions are proper. The first is an example of a π -institution which is syntactically family algebraizable but not syntactically family antialgebraizable.

Example 1078 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically family antialgebraizable π -institution which fails to be syntactically family algebraizable.

Example 1079 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1071 relates these two chiral sorts of syntactic family (anti)algebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1080 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if it is syntactically equivalential and family truth equational.*
- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if it is syntactically protoalgebraic and strongly family truth equational.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by definition, it is equivalential, with a locally Leibniz binary reflexive core, and family c-reflective, with an adequate Suszko core, if and only if, by Theorems 989 and 848, is it syntactically equivalential and family truth equational.

- (b) We have that $\mathcal{I}$ is syntactically family antialgebraizable if and only if, by definition, it is protoalgebraic, with a Leibniz reflexive core, and family c-reflective, with an adequate unary Suszko core, if and only if, by Theorems 805 and 1003, is it syntactically protoalgebraic and strongly family truth equational. ■

An alternative characterization, analogous to that of Theorem 1072, relates the syntactic with the corresponding semantic notions.

Theorem 1081 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if it is family algebraizable and $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified.*
- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if it is family algebraizable and $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by definition, it is equivalential and family c-reflective and, moreover, it has a locally Leibniz binary reflexive core and an adequate Suszko core. This happens if and only if, by definition, it is family algebraizable and $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified.
- (b) Similarly, $\mathcal{I}$ is syntactically family antialgebraizable if and only if, by definition, it is equivalential and family c-reflective and, moreover, it has a Leibniz reflexive core and an adequate unary Suszko core. This happens if and only if, by definition, it is family algebraizable and $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified. ■

The characterization in terms of semantic properties and preceding work on transference of properties from theory families to filter families on arbitrary algebraic systems yield a transfer property for syntactic family (anti)-algebraizability.

Theorem 1082 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and family c-reflective.*
- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if it is $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families and family c-reflective.*

Proof: We prove only Part (a), since Part (b) is similar. We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by Theorem 1081, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and family algebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and family c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following result.

Theorem 1083 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if it is $R^{\mathcal{I}}\dot{S}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: Again we show only Part (a). Part (b) is similar. We have that $\mathcal{I}$ is syntactically family algebraizable if and only if, by Theorem 1081, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and family algebraizable if and only if, by Theorem 366, it is $\ddot{R}^{\mathcal{I}}S^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. ■

In terms of conjugate pairs of transformations, we get the following analog of Theorem 1075.

Theorem 1084 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if it is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ of transformations, with I^b natural.*
- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if it is equivalent to $\mathcal{Q}^{\mathcal{I}*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^{\mathcal{I}*}$ of transformations, with τ^b natural.*

Proof:

- (a) Suppose, first, that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, by Corollary 975, it is syntactically equivalential and, by Theorem 913, it is family truth equational. Thus, by Theorem 1080, it is syntactically family algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically family algebraizable. Then, by Theorem 1080, it is left truth equational and syntactically equivalential. Hence, by Theorem 915, it is syntactically WF prealgebraizable. Now it follows by Theorem 921 that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a pair $(\tau^b, \vec{I}^b)$, where I^b witnesses the syntactic equivalentiality and τ^b the syntactic family truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with I^b natural.

- (b) Suppose, first, that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, by Theorem 912, it is syntactically protoalgebraic and, by Theorem 913, it is strongly family truth equational. Thus, by Theorem 1080, it is syntactically family antialgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically family antialgebraizable. Then, by Theorem 1080, it is strongly left truth equational and syntactically protoalgebraic. Hence, by Theorem 915, it is syntactically WF prealgebraizable. Now it follows by Theorem 921 that $\mathcal{I}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a pair $(\tau^b, \vec{I}^b)$, where I^b witnesses the syntactic protoalgebraicity and τ^b the strong family truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with τ^b natural. ■

The equivalence of the π -institution with some equational π -structure via a conjugate pair of transformations exhibiting the required one-sided naturality condition suffices to ensure syntactic family (anti)algebraizability.

Theorem 1085 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if it is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural.*
- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if it is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural.*

Proof:

- (a) If $\mathcal{I}$ is syntactically family algebraizable, then, by Theorem 1084, it is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations with I^b natural. Suppose, conversely, that $\mathcal{I}$ is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, by Theorem 912, it is syntactically equational and, by Theorem 913, it is family truth equational. Therefore, by Theorem 1080, it is syntactically family algebraizable.
- (b) If $\mathcal{I}$ is syntactically family antialgebraizable, then, by Theorem 1084, it is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Suppose, conversely, that $\mathcal{I}$ is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, by Theorem 912, it is syntactically protoalgebraic and, by Theorem 913, it is strongly family truth equational. Therefore, by Theorem 1080, it is syntactically family antialgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following alternative characterization of syntactic family (anti)algebraizability.

Theorem 1086 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically family algebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an algebraic π -structure and I^b is natural.*
- (b) *$\mathcal{I}$ is syntactically family antialgebraizable if and only if there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{I}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an algebraic π -structure and τ^b is natural.*

Proof: The “only if” follows by Theorem 1085 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1085. ■

In this section we have introduced the three syntactic family algebraizability classes

In the next section, we shall introduce the remaining three syntactic algebraizability classes, namely those of the syntactically algebraizable π -institutions, in order to complete the syntactic algebraizability hierarchy that was described at the beginning of the section.

13.11 Syntactic Algebraizability

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified if:

- $\mathcal{I}$ has a locally Leibniz binary reflexive core;
- $\mathcal{I}$ has an adequate unary system core.

We say that $\mathcal{I}$ is **syntactically strongly algebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is equivalential (i.e., protoalgebraic and family extensional);
- $\mathcal{I}$ is system c-reflective.

An analog of Theorem 1071 provides an important characterization of syntactic strong algebraizability in terms of lower classes in the syntactic hierarchy.

Theorem 1087 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is syntactically equivalential and strongly system truth equational.*

Proof: We have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if, by definition, it is

- equivalential and has a locally Leibniz binary reflexive core;
- system c-reflective and has an adequate unary system core;

if and only if, by Theorems 989 and 1035, is it syntactically preequivalential and strongly system truth equational. ■

An analog of Theorem 1072 gives an alternative characterization of the syntactic notion in terms of the corresponding semantic notions.

Theorem 1088 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is (system) algebraizable and $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified.*

Proof: We have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if, by definition,

- it is equivalential and system c-reflective;
- it has a locally Leibniz binary reflexive core and an adequate unary system core;

if and only if, by definition, it is algebraizable and $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified. ■

This characterization in terms of semantic properties and preceding work on transference of properties from theory families/systems to filter families/systems on arbitrary algebraic systems yield another characterization of syntactic strong algebraizability analogous to that of Theorem 1073, which may also be viewed as a kind of transfer property for syntactically strongly algebraizable π -institutions.

Theorem 1089 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and system c-reflective.*

Proof: We have that $\mathcal{I}$ is syntactically strongly algebraizable if and only if, by Theorem 1088, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and algebraizable if and only if, by Theorem 349, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and system c-reflective. ■

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following analog of Theorem 1074.

Theorem 1090 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

Proof: We have that $\mathcal{I}$ is syntactically strongly (system) algebraizable if and only if, by Theorem 1088, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and algebraizable if and only if, by Theorem 365, it is $\ddot{R}^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}^*}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions. ■

Finally, in an analog of Theorem 1075, using conjugate pairs of transformations, we get

Theorem 1091 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}^*}$ of natural transformations.*

Proof: Suppose, first, that $\mathcal{I}$ is stable and $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a conjugate pair of natural transformations. Then, by Theorem 931, it is syntactically equivalential and, by Theorem 944, it is strongly system truth equational. Thus, by Theorem 1087, it is syntactically strongly algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically strongly algebraizable. Then, by Theorem 1087, it is syntactically equivalential and strongly system truth equational. Hence, by Theorem 925, it is syntactically weakly algebraizable. Now it follows by Theorem 929 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}^*}$ via a pair $(\tau^b, \vec{I}^b)$, where I^b witnesses the syntactic equivalentiality and τ^b the strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of natural transformations. ■

Analogously with Theorem 1076, the equivalence of the systemic skeleton with an equational π -structure via a conjugate pair of natural transformations, coupled with stability, suffices to ensure syntactic strong algebraizability.

Theorem 1092 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is stable and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of natural transformations.*

Proof: If $\mathcal{I}$ is syntactically strongly algebraizable, then, by Theorem 1091, it is stable and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair of natural transformations. Suppose, conversely, that $\mathcal{I}$ is stable and that its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair of natural transformations. Then, by Theorem 931, it is syntactically equivalential and, by Theorem 932, it is strongly system truth equational. Therefore, by Theorem 1087, it is syntactically strongly algebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1074, providing an alternative characterization of syntactic strong algebraizability.

Theorem 1093 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically strongly algebraizable if and only if it is stable and there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of natural transformations, where $\mathcal{Q}$ is an equational π -structure.*

Proof: The “only if” follows by Theorem 1092 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1092. ■

As with all other strong (pre)algebraizability classes, studied before, below the class of syntactically strongly algebraizable π -institutions sit two wider classes obtained by weakening the naturality requirement either on the side of the witnesses of prealgebraicity or on the side of the witnesses of truth equationality. We obtain, thus, the classes of *syntactically algebraizable* and *syntactically antialgebraizable* π -institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -**fortified** if:

- $\mathcal{I}$ has a locally Leibniz binary reflexive core;
- $\mathcal{I}$ has an adequate system core.

$\mathcal{I}$ is **syntactically algebraizable** if:

- $\mathcal{I}$ is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is equivalential;
- $\mathcal{I}$ is system c-reflective.

Similarly, $\mathcal{I}$ is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -**fortified** if:

- $\mathcal{I}$ has a Leibniz reflexive core;
- $\mathcal{I}$ has an adequate unary system core.

$\mathcal{I}$ is **syntactically antialgebraizable** if:

- $\mathcal{I}$ is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified;
- $\mathcal{I}$ is protoalgebraic;
- $\mathcal{I}$ is system c-reflective.

We now conclude the chapter by formulating analogs of many of the results proven above for syntactic strong algebraizability for these two new classes of π -institutions.

Again, we start with the following observations:

- Equivalentiality implies protoalgebraicity.

- Under protoalgebraicity, $\ddot{R}^{\mathcal{I}}$ locally Leibniz implies $R^{\mathcal{I}}$ Leibniz.
- $\dot{Z}^{\mathcal{I}}$ adequate implies $Z^{\mathcal{I}}$ adequate.

From these, we get the following hierarchical relations between the three classes in the second-from-top tier of the syntactic algebraizability hierarchy.

Examples are in order to show that the two inclusions are proper. The first is an example of a π -institution which is syntactically algebraizable but not syntactically antialgebraizable.

Example 1094 EXAMPLE NOT FOUND YET!!

Next, we give an example of a syntactically antialgebraizable π -institution which fails to be syntactically algebraizable.

Example 1095 EXAMPLE NOT FOUND YET!!

The following analog of Theorem 1087 relates the two chiral types of syntactic algebraizability with various classes introduced previously, providing some important characterizations.

Theorem 1096 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is syntactically equivalential and system truth equational.*
- (b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is syntactically protoalgebraic and strongly system truth equational.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically algebraizable if and only if, by definition, it is equivalential, with a locally Leibniz binary reflexive core, and system c-reflective, with an adequate system core, if and only if, by Theorems 989 and 889, is it syntactically equivalential and system truth equational.
- (b) We have that $\mathcal{I}$ is syntactically antialgebraizable if and only if, by definition, it is protoalgebraic, with a Leibniz reflexive core, and system c-reflective, with an adequate unary system core, if and only if, by Theorems 805 and 1035, is it syntactically protoalgebraic and strongly system truth equational.

■

An alternative characterization, analogous to that of Theorem 1088, relates the syntactic with the corresponding semantic notions.

Theorem 1097 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is algebraizable and $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified.*
- (b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is weakly algebraizable and $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified.*

Proof:

- (a) We have that $\mathcal{I}$ is syntactically algebraizable if and only if, by definition, it is equivalential and system c-reflective and, moreover, it has a locally Leibniz binary reflexive core and an adequate system core. This happens if and only if, by definition, it is algebraizable and $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified.
- (b) Similarly, $\mathcal{I}$ is syntactically antialgebraizable if and only if, by definition, it is protoalgebraic and system c-reflective and, moreover, it has a Leibniz reflexive core and an adequate unary system core. This happens if and only if, by definition, it is weakly algebraizable and $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified.

■

The properties defining syntactic (anti)algebraizability transfer from theory families/systems to filter families/systems on arbitrary algebraic systems. More precisely, we obtain the following analog of Theorem 1089.

Theorem 1098 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and system c-reflective.*
- (b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families and system c-reflective.*

Proof: We prove only Part (a). Part (b) is similar. We have that $\mathcal{I}$ is syntactically algebraizable if and only if, by Theorem 1097, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and algebraizable if and only if, by Theorem 363, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and, for

every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{I}$ -filter families, family extensional and system c-reflective. $\blacksquare$

Turning now to characterizations involving property preserving mappings between posets of filter families and of congruence systems, we have the following analog of Theorem 1090.

Theorem 1099 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism that commutes with inverse logical extensions.

- (b) *$\mathcal{I}$ is syntactically antialgebraizable if and only if it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof:

- (a) $\mathcal{I}$ is syntactically algebraizable if and only if, by Theorem 1097, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified and algebraizable if and only if, by Theorem 365, it is $\ddot{R}^{\mathcal{I}}Z^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism that commutes with inverse logical extensions.
- (b) $\mathcal{I}$ is syntactically antialgebraizable if and only if, by Theorem 1097, it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified and weakly algebraizable if and only if, by Theorem 298, it is $R^{\mathcal{I}}\dot{Z}^{\mathcal{I}}$ -fortified, stable and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \text{FiSys}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism. $\blacksquare$

Finally, in terms of conjugate pairs of transformations, we get the following analog of Theorem 1091.

Theorem 1100 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically algebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}}$ of transformations, with I^b natural.*

- (b) $\mathcal{I}$ is syntactically antialgebraizable if and only if it is stable and its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair $(\tau^b, I^b) : \mathcal{K}^{\mathcal{I}} \rightleftarrows \mathcal{Q}^{\mathcal{I}}$ of transformations, with τ^b natural.

Proof:

- (a) Suppose, first, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, by Theorem 931, it is syntactically equivalential and, by Theorem 932, it is system truth equational. Thus, by Theorem 1096, it is syntactically algebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically algebraizable. Then, by Theorem 1096, it is syntactically equivalential and system truth equational. Hence, by Theorem 925, it is syntactically weakly algebraizable. Now it follows by Theorem 929 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a pair $(\tau^b, \overset{\leftrightarrow}{I}^b)$, where I^b witnesses the syntactic equivalentiality and τ^b the system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with I^b natural.

- (b) Suppose, first, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, by Theorem 931, it is syntactically protoalgebraic and, by Theorem 932, it is strongly system truth equational. Thus, by Theorem 1096, it is syntactically antialgebraizable.

Suppose, conversely, that $\mathcal{I}$ is syntactically antialgebraizable. Then, by Theorem 1096, it is syntactically protoalgebraic and strongly system truth equational. Hence, by Theorem 925, it is syntactically weakly algebraizable. Now it follows by Theorem 929 that $\mathcal{K}^{\mathcal{I}}$ is equivalent to $\mathcal{Q}^{\mathcal{I}}$ via a pair $(\tau^b, \overset{\leftrightarrow}{I}^b)$, where I^b witnesses the syntactic protoalgebraicity and τ^b the strong system truth equationality of $\mathcal{I}$, and, hence, by definition, they constitute a conjugate pair of transformations, with τ^b natural. ■

The equivalence of the systemic skeleton with an equational π -structure via a conjugate pair of transformations, exhibiting the required one-sided naturality condition, is sufficient to ensure syntactic system (anti)algebraizability. This constitutes an analog of Theorem 1092.

Theorem 1101 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) $\mathcal{I}$ is syntactically algebraizable if and only if it is stable and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural.

- (b) $\mathcal{I}$ is syntactically antialgebraizable if and only if it is stable and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural.

Proof:

- (a) If $\mathcal{I}$ is syntactically algebraizable, then, by Theorem 1100, it is stable and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Suppose, conversely, that $\mathcal{I}$ is stable and that its systemic skeleton $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with I^b natural. Then, by Proposition 931, it is syntactically equivalential and, by Theorem 932, it is system truth equational. Therefore, by Theorem 1096, it is syntactically algebraizable.
- (b) If $\mathcal{I}$ is syntactically antialgebraizable, then, by Theorem 1100, it is stable and its systemic skeleton is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Suppose, conversely, that $\mathcal{I}$ is stable and that $\mathcal{K}^{\mathcal{I}}$ is equivalent to an equational π -structure via a conjugate pair (τ^b, I^b) of transformations, with τ^b natural. Then, by Proposition 931, it is syntactically protoalgebraic and, by Theorem 932, it is strongly system truth equational. Therefore, by Theorem 1096, it is syntactically antialgebraizable. ■

Finally, in terms of order isomorphisms between theory family lattices, we have the following analog of Theorem 1093, giving an alternative characterization of syntactically (anti)algebraizable π -institutions.

Theorem 1102 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) $\mathcal{I}$ is syntactically algebraizable if and only if it is stable and there exists a transformational order isomorphism $h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q})$, induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an equational π -structure and I^b is natural.
- (b) $\mathcal{I}$ is syntactically antialgebraizable if and only if it is stable and there exists a transformational order isomorphism

$$h : \mathbf{ThFam}(\mathcal{K}^{\mathcal{I}}) \rightarrow \mathbf{ThFam}(\mathcal{Q}),$$

induced by a conjugate pair (τ^b, I^b) of transformations, where $\mathcal{Q}$ is an equational π -structure and τ^b is natural.

Proof: The “only if” follows by Theorem 1101 and Theorem 896. The “if” is given by Theorem 904 and Theorem 1101. ■

To close the chapter, we have some class separating work to do. First of all, since we have now described in detail the six classes of the syntactic algebraizability hierarchy, it is only appropriate to pause and look for examples that separate the family algebraizability classes, i.e., those in the top-most tier, from the algebraizability classes, that is those immediately below them. In other words, we are looking for examples that show that the vertical arrows in the accompanying diagram

represent, in fact, proper inclusions. We can do this all at once by exhibiting an example of a syntactically strongly algebraizable π -institution which is neither syntactically family algebraizable nor syntactically family antialgebraizable.

Example 1103 EXAMPLE NOT FOUND YET!

Last, since the syntactic algebraizability classes, shown in the bottom row of the preceding diagram, dominate the syntactic left prealgebraizability classes in the 12-class hierarchy, we also need examples to separate syntactically algebraizable from syntactically left prealgebraizable π -institutions, i.e., examples showing that the middle three (longish) vertical arrows in the

diagram

represent proper inclusions. Again, in a single strike, this can be accomplished by providing an example of a syntactically strongly left prealgebraizable π -institution which is neither syntactically algebraizable nor syntactically antialgebraizable.

Example 1104 EXAMPLE NOT FOUND YET!

Chapter 14

The Syntactic Leibniz Hierarchy: Basement I

14.1 Introduction

In this chapter, the study of syntactic analogs of the semantic hierarchies studied in Chapter 6 are undertaken. These fall under the classes of the syntactic truth equationality subhierarchy detailed in Sections 11.6-11.10. Thus, they occupy positions close to the right bottom of the algebraic hierarchy of π -institutions. The study of both semantic and syntactic properties of those classes takes after a very similar study in the context of sentential logics initiated in Moraschini's Ph.D. Dissertation [90].

In Section 14.2, we study *rough* or *narrow truth equationality*, the syntactic analog of rough and of narrow complete reflectivity, studied in Sections 6.8-6.9. Rough truth equationality has the same relation to truth equationality as rough c-reflectivity has to c-reflectivity. That is, it is essentially truth equationality applied only to theory families all of whose components are nonempty.

In summarizing some of the key concepts, we recall that, for a theory family T of a π -institution $\mathcal{I}$, $\tilde{T}$ denotes the theory family that results from T by replacing all empty components by the corresponding entire sets of sentences. Moreover, we denote by $\text{ThFam}^{\sharp}(\mathcal{I})$, the collection of all theory families of $\mathcal{I}$ all of whose components are nonempty. Notice that, if $\mathcal{I}$ has theorems, then we have, for every theory family T , $\tilde{T} = T$ and, also, $\text{ThFam}^{\sharp}(\mathcal{I}) = \text{ThFam}(\mathcal{I})$. Among others, an important observation is that, for every theory family T of $\mathcal{I}$, $\Omega(\tilde{T}) = \Omega(T)$. These definitions and observations, and a quite detailed analysis of all relevant concepts, were the subject of the first sections of Chapter 6.

We say that a π -institution $\mathcal{I}$ is *roughly* or *narrowly (family) truth equational* if there exists a collection $\tau^{\flat} : (\text{SEN}^{\flat})^{\omega} \rightarrow (\text{SEN}^{\flat})^2$ in $N^{\flat}$, with a single distinguished argument, such that, for all theory families T of $\mathcal{I}$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi/\Omega_{\Sigma}(T) \in \tilde{T}_{\Sigma}/\Omega_{\Sigma}(T) \quad \text{iff} \quad \tau^{\mathcal{F}/\Omega(T)}[\phi/\Omega_{\Sigma}(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}.$$

This condition is equivalent to the assertion that for all theory families T of $\mathcal{I}$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\flat}[\phi] \leq \Omega(T).$$

Truth equationality is separated from rough truth equationality by the existence of theorems. More precisely, it is shown that a π -institution $\mathcal{I}$ is truth equational if and only if it is roughly truth equational and has theorems. Rough truth equationality implies rough family c-reflectivity. To intrinsically characterize rough truth equationality, we use a specially adapted version of the Suszko core defined by restricting attention to theory families without empty components. The *rough Suszko core* $S^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is defined by

$$S^{\mathcal{I}^{\sharp}} = \{\sigma^{\flat} \in N^{\flat} : (\forall T \in \text{ThFam}(\mathcal{I}))(\sigma^{\flat}[\tilde{T}] \leq \tilde{\Omega}^{\mathcal{I}}(\tilde{T}))\}.$$

Equivalently, $S^{\mathcal{I}^\sharp} = \{\sigma^b \in N^b : (\forall T \in \text{ThFam}^\sharp(\mathcal{I}))(\sigma^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T))\}$. It always holds that, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $T \leq \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T))$. If the reverse inclusion happens to be valid, we say that $S^{\mathcal{I}^\sharp}$ is *soluble*. Solubility is equivalent to the statement that, for all $T \in \text{ThFam}(\mathcal{I})$, $\tilde{T} = \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T))$. We show that $\mathcal{I}$ is roughly truth equational if and only if its rough Suszko core is soluble. Another characterization asserts that $\mathcal{I}$ is roughly truth equational if and only if $S^{\mathcal{I}^\sharp}$ roughly defines theory families, in the sense that, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $T = \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T))$.

In a π -institution $\mathcal{I}$, we have, in general, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{\Omega(T) : S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T)\} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

If the reverse inclusion holds, then we say that $S^{\mathcal{I}^\sharp}$ is *adequate*. Solubility of $S^{\mathcal{I}^\sharp}$ implies its adequacy. Provided that $\mathcal{I}$ is roughly family c-reflective, the reverse implication also holds, that is, adequacy of $S^{\mathcal{I}^\sharp}$ implies its solubility. These implications enable us to obtain a characterization of rough truth equationality to the effect that $\mathcal{I}$ is roughly truth equational if and only if it is roughly family c-reflective and has an adequate rough Suszko core. Section 14.2 closes with a result that, besides providing yet another characterization, may be viewed as a transfer theorem. It asserts that $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is roughly truth equational, with witnessing equations $\tau^{\mathcal{A}}$.

In Section 14.3, we study *rough left truth equationality*. It has the same relation to rough left c-reflectivity, its semantic counterpart, as rough truth equationality has to rough c-reflectivity. Additionally, it has the same relation to rough truth equationality as left truth equationality has to truth equationality. Roughly speaking, rough left truth equationality results from left truth equationality by bypassing theory families with empty components.

A π -institution $\mathcal{I}$ is *roughly left truth equational* if there exists a collection $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for every theory family T , all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in \overleftarrow{\tilde{T}}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

According to this definition, $\mathcal{I}$ is left truth equational if and only if it is roughly left truth equational and has theorems. It turns out that, if $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b , then, for all theory families T , $\overleftarrow{\tilde{T}} = \overleftarrow{\tau^b}(\Omega(T))$. Recalling that $\mathcal{I}$ is roughly left c-reflective if, for every collection $\mathcal{T} \cup \{T'\}$ of theory families

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{\tilde{T}} \leq \overleftarrow{\tilde{T}'},$$

we can show that rough left truth equationality implies rough left c-reflectivity. To characterize intrinsically rough left truth equationality, we rely on the rough left Suszko core. The *rough left Suszko core* $\tilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ is the collection of all natural transformations σ^b in N^b , such that, for every signature Σ and all Σ -sentences ϕ , $\sigma_\Sigma^b[\phi] \leq \bigcap \{ \Omega(T) : \phi \in \tilde{T}_\Sigma \}$. The definition implies that, for every theory family T , $\tilde{T} \leq \tilde{L}^{\mathcal{I}}(\Omega(T))$. If the reverse inclusion is valid, we say that $\tilde{L}^{\mathcal{I}}$ is *left soluble*. Left solubility of $\tilde{L}^{\mathcal{I}}$ intrinsically characterizes rough left truth equationality. Another characterization involves rough definability of theory families up to arrow, in the sense that, for every theory family T , $\tilde{T} = \tilde{L}^{\mathcal{I}}(\Omega(T))$.

The rough left Suszko core $\tilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ satisfies, in general, the property that, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : \tilde{L}_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T) \} \leq \bigcap \{ \Omega(T) : \phi \in \tilde{T}_\Sigma \}.$$

If the reverse inclusion is valid, then we say that $\tilde{L}^{\mathcal{I}}$ is *left adequate*. Left solubility of $\tilde{L}^{\mathcal{I}}$ implies its left adequacy. If $\mathcal{I}$ happen to be left c-reflective, then left adequacy implies left solubility as well. These results yield that $\mathcal{I}$ is roughly left truth equational if and only if it is roughly left c-reflective and has a left adequate rough left Suszko core. The section closes with a result asserting that rough left truth equationality transfers, in a sense similar to that detailed previously for rough truth equationality.

In Section 14.4, we look at an alternative way to deal with theory families having empty components. Whereas rough left truth equationality, studied in Section 14.3, picks the largest rough representative of a given theory family, if the family happens to have empty components, *narrow left truth equationality* ignores theory families with empty components by working with the collection $\text{ThFam}^{\sharp}(\mathcal{I})$. Accordingly, a π -institution $\mathcal{I}$ is *narrowly left truth equational* if there exists a collection $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

By paying the price of introducing rough representatives on the left (and implicitly on the right), we may write this condition equivalently as the stipulation that, for all $T \in \text{ThFam}(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

As was the case with rough left truth equationality, we get, here also, that a π -institution $\mathcal{I}$ is left truth equational if and only if it is narrowly left truth equational and has theorems. Narrow left truth equationality affords

expressions for theory families in terms of Leibniz congruence systems by the rules $\overleftarrow{T} = \overleftarrow{\tau^b}(\Omega(T))$, for all $T \in \text{ThFam}^{\mathcal{I}}(\mathcal{I})$, and, again, avoiding the restriction, $\overleftarrow{\overleftarrow{T}} = \overleftarrow{\tau^b}(\Omega(T))$, for all $T \in \text{ThFam}(\mathcal{I})$. Additionally, narrow left truth equationality implies narrow left c-reflectivity, its semantic counterpart. To intrinsically characterize narrow left truth equationality, another modification of the left Suszko core is introduced. The *narrow left Suszko core* $L^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ consists of all σ^b in N^b , such that, for all $T \in \text{ThFam}^{\mathcal{I}}(\mathcal{I})$, $\sigma^b[\overleftarrow{T}] \leq \tilde{\Omega}^{\mathcal{I}}(T)$. This definition ensures that, for all $T \in \text{ThFam}^{\mathcal{I}}(\mathcal{I})$, $\overleftarrow{T} \leq \overleftarrow{L^{\mathcal{I}^{\sharp}}}(\Omega(T))$. If the reverse inclusion is valid, we say that $L^{\mathcal{I}^{\sharp}}$ is *left soluble*. Let solubility of $L^{\mathcal{I}^{\sharp}}$ characterizes narrow left truth equationality. Another characterization asserts that $\mathcal{I}$ is narrowly left truth equational if and only if $L^{\mathcal{I}^{\sharp}}$ narrowly defines theory families of $\mathcal{I}$ up to arrow, in the sense that, for all $T \in \text{ThFam}^{\mathcal{I}}(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^{\mathcal{I}^{\sharp}}}(\Omega(T))$.

In general, the narrow left Suszko core satisfies, for all signatures Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\overrightarrow{\phi})).$$

We say that $L^{\mathcal{I}^{\sharp}}$ is *left adequate* if the reverse inclusion is also valid. Left solubility of $L^{\mathcal{I}^{\sharp}}$ implies its left adequacy. The converse implication holds, provided that $\mathcal{I}$ is narrowly left c-reflective. Using these results, we show that $\mathcal{I}$ is narrowly left truth equational if and only if it is narrowly left c-reflective and has a left adequate narrow left Suszko core. The section ends with a transfer theorem to the effect that $\mathcal{I}$ is narrowly left truth equational if and only if, for every **F**-algebraic system $\mathcal{A}$, all $T \in \text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A})$, all signatures Σ and all Σ -sentences ϕ , $\phi \in \overleftarrow{T}_{\Sigma}$ if and only if $\tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T)$.

In Section 14.5, we study *rough system truth equationality*. This property is the syntactic analog of rough system c-reflectivity and lies below rough left truth equationality. It is defined similarly to system truth equationality, but avoids theory systems with empty components, by using roughly equivalent representatives. A π -institution $\mathcal{I}$ is *roughly system truth equational* if there exists a collection $\tau^b : (\text{SEN}^b)^{\omega} \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all theory systems T , all signatures Σ , and all Σ -sentences ϕ ,

$$\phi \in \tilde{T}_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(T).$$

A π -institution is system truth equational if and only if it is roughly system truth equational and has theorems. Rough system truth equationality yields, for every theory system T , an expression of $\tilde{T}$ in terms of the Leibniz congruence system of T , via the witnessing equations, $\tilde{T} = \overleftarrow{\tau^b}(\Omega(T))$. This gives that rough system truth equationality implies rough system c-reflectivity, its semantic counterpart. In this case, to derive an intrinsic characterization of rough system truth equationality, we introduce the *rough system core* $\tilde{Z}^{\mathcal{I}}$ of

a π -institution $\mathcal{I}$. It consists of all natural transformations σ^b in N^b , such that, for every signature Σ and all Σ -sentences ϕ ,

$$\sigma_\Sigma^b[\phi] \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_\Sigma \}.$$

This definition implies that, for every theory system T , $\tilde{T} \leq \overleftarrow{\tilde{Z}^\mathcal{I}}(\Omega(T))$. $\tilde{Z}^\mathcal{I}$ is said to be *soluble* if the reverse inclusion is also valid. Here, also, we have that $\mathcal{I}$ is roughly system truth equational if and only if $\tilde{Z}^\mathcal{I}$ is soluble. Another characterization asserts that $\mathcal{I}$ is roughly system truth equational if and only if $\tilde{Z}^\mathcal{I}$ roughly defines theory systems, in the sense that, for all $T \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tilde{Z}^\mathcal{I}}(\Omega(T))$.

Similarly to the case of rough left truth equationality, the rough system core $\tilde{Z}^\mathcal{I}$ of $\mathcal{I}$ satisfies, in general, for all signatures Σ and all Σ -sentences ϕ ,

$$\begin{aligned} \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \tilde{Z}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \\ \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_\Sigma \}. \end{aligned}$$

If the reverse inclusion is also valid, then we say that the rough system core is *adequate*. Solubility of $\tilde{Z}^\mathcal{I}$ implies its adequacy. Moreover, the converse holds if $\mathcal{I}$ happens to be roughly system c-reflective. It follows that $\mathcal{I}$ is roughly system truth equational if and only if it is roughly system c-reflective and has an adequate rough system core. the section concludes with a transfer theorem for rough system truth equationality similar in spirit to the one described previously for narrow left truth equationality.

In Section 14.6, we switch to *narrow system truth equationality*. As was the case with narrow left truth equationality, narrow system truth equationality results from system truth equationality by bypassing theory systems with empty components. We say that a π -institution $\mathcal{I}$ is *narrowly system truth equational* if there exists a collection $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for every theory system T , for which $\tilde{T}$ is also a theory system, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Another, equivalent, formulation asserts that, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

A π -institution $\mathcal{I}$ is system truth equational if and only if it is narrowly truth system truth equational and has theorems. Recall that the analogous statement is also valid for rough system truth equationality in place of narrow system truth equationality. Narrow system truth equationality via witnessing equations τ^b is equivalent to having, for all $T \in \text{ThSys}(\mathcal{I})$, with $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tau^b}(\Omega(T))$ and, also, to having, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$

$T = \overleftarrow{\tau^b}(\Omega(T))$. These expressions allow us, with little effort, to show that narrow system truth equationality implies narrow system c-reflectivity, which constitutes its semantic analog. To intrinsically characterize narrow system truth equationality, we use another modification of the system core, called *narrow system core* and denoted by $Z^{\mathcal{I}^\sharp}$, consisting of all those natural transformations σ^b in N^b , such that, for every theory system T , with $\tilde{T}$ also a theory system, $\sigma^b[\tilde{T}] \leq \widehat{\Omega}^{\mathcal{I}}(T)$, where $\widehat{\Omega}^{\mathcal{I}}$ denotes the systemic Suszko operator associated with the π -institution $\mathcal{I}$. An equivalent definition asserts that $Z^{\mathcal{I}^\sharp}$ consists of those natural transformations σ^b in N^b , such that, for every $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\sigma^b[T] \leq \widehat{\Omega}^{\mathcal{I}}(T)$. It can be seen that, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $T \leq \overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T))$. *Solubility* of $Z^{\mathcal{I}^\sharp}$ is the property that holds when the reverse inclusion is also valid. Equivalently, $Z^{\mathcal{I}^\sharp}$ is soluble if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, with $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T))$. Solubility of the narrow system core intrinsically characterizes narrow system truth equationality. Another characterization states that $\mathcal{I}$ is narrowly system truth equational if and only if $Z^{\mathcal{I}^\sharp}$ narrowly defines theory systems, i.e., for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T))$.

We mentioned that narrow system truth equationality implies narrow system c-reflectivity. To pinpoint the separating line between the two classes, we use another property of the narrow system core, akin to the property of adequacy of the system core. To define it, we first need, once more, a modified version of the systemic Suszko operator $\widehat{\Omega}^{\mathcal{I}}$, called the *narrow systemic Suszko operator*, given, for all $T \in \text{ThSys}(\mathcal{I})$, by

$$\widehat{\Omega}^{\mathcal{I}^\sharp}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}^\sharp(\mathcal{I}) \}.$$

If $T \in \text{ThSys}^\sharp(\mathcal{I})$, then $\widehat{\Omega}^{\mathcal{I}^\sharp}(T) = \widehat{\Omega}^{\mathcal{I}}(T)$. In general, the narrow systemic Suszko operator satisfies, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})).$$

If the reverse inclusion happen to be valid, then we say that $Z^{\mathcal{I}^\sharp}$ is *adequate*. Solubility of $Z^{\mathcal{I}^\sharp}$ implies its adequacy and, moreover, if $\mathcal{I}$ is narrowly system c-reflective, the reverse implication also holds. These yield that a π -institution $\mathcal{I}$ is narrowly system truth equational if and only if it is narrowly system c-reflective and has an adequate narrow system core. This section ends as well with a transfer theorem for narrow system truth equationality.

In Section 14.7, the last section of the chapter, we study the availability and some properties of *natural theorems*. The reason they are studied here is that availability of natural theorems is a property stronger than having theorems and the way used to characterize availability of natural theorems inside the class of π -institutions with theorems is reminiscent of the way truth equationality is characterized in the class of c-reflective π -institutions. Recall that, by convention, if a π -institution $\mathcal{I}$ has theorems, then, for every

signature Σ , $\text{Thm}_\Sigma(\mathcal{I}) := C_\Sigma(\emptyset) \neq \emptyset$. *Having natural theorems* is a stronger property defined by the stipulation that there exists a natural transformation ϑ^b in N^b , such that, for all signatures Σ and all tuples of Σ -sentences $\vec{\phi}$ of appropriate arity,

$$\vartheta_\Sigma^b(\vec{\phi}) \in \text{Thm}_\Sigma(\mathcal{I}).$$

The collection of natural theorems of $\mathcal{I}$ is denoted by $\text{NThm}(\mathcal{I})$. We show that, if $\mathcal{I}$ has natural theorems, then it has at least one that is at most unary. A characterization theorem asserts that ϑ^b is a natural theorem if and only if, for every theory family T , all signatures Σ and all Σ -sentences $\phi, \vec{\chi}$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \in \lambda_\Sigma(T).$$

Further, it is shown that, if ϑ^b is a natural theorem, then, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\vartheta^{\mathcal{A}}$ is a natural theorem of $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$. This allows another characterization of natural theorems. Namely, ϑ^b is a natural theorem if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, all $\mathcal{I}$ -filter families T of $\mathcal{A}$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in T_\Sigma \quad \text{iff} \quad \langle \phi, \vartheta_\Sigma^{\mathcal{A}}(\vec{\chi}) \rangle \in \widetilde{\lambda}_\Sigma^{\mathcal{I}, \mathcal{A}}(T), \text{ for all } \vec{\chi} \in \text{SEN}(\Sigma).$$

Based on this, we may insert an intermediate step between the availability of natural theorems and the availability of theorems. More precisely, if $\mathcal{I}$ has natural theorems, there exists $\tau^b : (\text{SEN}^b)^k \rightarrow (\text{SEN}^b)^2$ in N^b , such that, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, all $\mathcal{I}$ -filter families T of $\mathcal{A}$, all signatures Σ and all Σ -sentences ϕ ,

$$\phi \in T_\Sigma \quad \text{iff} \quad (\forall \vec{\chi} \in \text{SEN}(\Sigma))(\tau_\Sigma^{\mathcal{A}}(\phi, \vec{\chi}) \subseteq \widetilde{\lambda}_\Sigma^{\mathcal{I}, \mathcal{A}}(T))$$

and, moreover, if the displayed condition holds, then $\mathcal{I}$ has theorems. To clarify further the relationship between the existence of theorems and that of natural theorems, we introduce an “analog” of the Suszko core, called the *Lindenbaum core*, because the Lindenbaum operator $\widetilde{\lambda}^{\mathcal{I}}$ is the analogous local equivalence operator to the Suszko congruence operator $\widetilde{\Omega}^{\mathcal{I}}$ (see the table at the end of Section 2.11). The *Lindenbaum core* $F^{\mathcal{I}}$ of a π -institution $\mathcal{I}$ consists of all natural transformations σ^b in N^b , such that, for all theory families T , all signatures Σ and all Σ -sentences $\vec{\chi}$,

$$\{\langle \phi, \sigma_\Sigma^b(\vec{\chi}) \rangle : \phi \in T_\Sigma\} \subseteq \widetilde{\lambda}_\Sigma^{\mathcal{I}}(T).$$

The Lindenbaum operator is denoted by $F^{\mathcal{I}}$ as the L is not available because of the left Suszko core $L^{\mathcal{I}}$ and the F is a reminder of the Frege operator, which is the basic equivalence operator on which the Lindenbaum operator is built. We show that, if $\mathcal{I}$ has natural theorems, then $F^{\mathcal{I}} = \text{NThm}(\mathcal{I})$. In general, for every signature Σ and all Σ -sentences ϕ ,

$$\bigcap \{ \lambda(T) : \{\langle \phi, F_\Sigma^{\mathcal{I}}(\vec{\chi}) \rangle : \vec{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_\Sigma(T) \} \subseteq \widetilde{\lambda}^{\mathcal{I}}(C(\phi)).$$

If the reverse inclusion is valid, then we say that the Lindenbaum core $F^{\mathcal{I}}$ is *adequate*. This property is significant because it delineates the boundary between having theorems and having natural theorems. Indeed, it is shown that $\mathcal{I}$ has natural theorems if and only if it has theorems and its Lindenbaum core is adequate. The section (and the chapter) concludes with a theorem to the effect that availability of natural theorems transfers from a π -institution to all $\mathcal{I}$ -gmatrix families of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.

14.2 Rough/Narrow Truth Equationality

In this section, we study *rough/narrow truth equationality*, the syntactic analog of rough c-reflectivity, which, recalling Corollary 482, coincides with narrow c-reflectivity. It has the same relation to truth equationality as rough c-reflectivity has to c-reflectivity. In other words, it mimics truth equationality, but it is applied only to theory families of a π -institution all of whose components are nonempty.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **roughly** or **narrowly (family) truth equational** if there exists $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi/\Omega_\Sigma(T) \in \tilde{T}_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}.$$

Recall that, by Proposition 369, for every $T \in \text{ThFam}(\mathcal{I})$, $\Omega(\tilde{T}) = \Omega(T)$. Thus, $\Omega(T)$ is compatible with $\tilde{T}$ and, hence, the preceding definition makes sense. The collection $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b is referred to as a set of **witnessing equations** (of/for the rough/narrow truth equationality of $\mathcal{I}$).

Paralleling Proposition 817, we get the following alternative characterization.

Proposition 1105 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a collection of natural transformations in N^b , with a single distinguished argument. $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,*

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Proof: Suppose $\mathcal{I}$ is roughly truth equational and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in \tilde{T}_\Sigma & \quad \text{iff} \quad \phi/\Omega_\Sigma(T) \in \tilde{T}_\Sigma/\Omega_\Sigma(T) \quad (\text{Proposition 369 and compatibility}) \\ & \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{rough truth equationality}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{by definition}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T). \end{aligned}$$

Suppose, conversely, that the given condition holds. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi/\Omega_\Sigma(T) \in \tilde{T}_\Sigma/\Omega_\Sigma(T) & \text{ iff } \phi \in \tilde{T}_\Sigma \quad (\text{Proposition 369 and compatibility}) \\ & \text{ iff } \tau_\Sigma^b[\phi] \leq \Omega(T) \quad (\text{by hypothesis}) \\ & \text{ iff } \tau_\Sigma^b[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \\ & \text{ iff } \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}. \quad (\text{definition}) \end{aligned}$$

Therefore, $\mathcal{I}$ is roughly truth equational. $\blacksquare$

It is not difficult to see that an alternative way to express rough truth equationality is to assert the same condition that defines truth equationality, excluding, however, those theory families with at least one empty component.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 6 that we denote by $\text{ThFam}^\sharp(\mathcal{I})$ the collection of all theory families T of $\mathcal{I}$, such that $T_\Sigma \neq \emptyset$, for all $\Sigma \in |\mathbf{Sign}^b|$:

$$\text{ThFam}^\sharp(\mathcal{I}) = \{T \in \text{ThFam}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^b|)(T_\Sigma \neq \emptyset)\}.$$

Recall, also, that, if $\mathcal{I}$ has theorems, then $\text{ThFam}^\sharp(\mathcal{I}) = \text{ThFam}(\mathcal{I})$. In particular, this is the case if $\mathcal{I}$ happens to be truth equational.

Proposition 1106 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ a collection of natural transformations in N^b , with a single distinguished argument. $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,*

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then $\tilde{T} = T$, whence, by Proposition 1105, $\phi \in T_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$.

Suppose, conversely, that the displayed condition holds. Consider $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then, since, by definition of $\tilde{T}$, we have $\tilde{T} \in \text{ThFam}^\sharp(\mathcal{I})$, we get, by hypothesis, $\phi \in \tilde{T}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(\tilde{T})$, whence, using Proposition 369, we conclude that $\phi \in \tilde{T}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Therefore, $\mathcal{I}$ is roughly truth equational. $\blacksquare$

As a corollary, we obtain the following key relationship between rough truth equationality and truth equationality.

Corollary 1107 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if it is roughly truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , and that it has theorems. Availability of theorems implies that $\text{ThFam}^{\sharp}(\mathcal{I}) = \text{ThFam}(\mathcal{I})$. Thus, by Proposition 1106, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is truth equational, with the same witnessing equations τ^b .

Assume, conversely, that $\mathcal{I}$ is truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThFam}(\mathcal{I})$, and, hence, a fortiori, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Hence, again by Proposition 1106, $\mathcal{I}$ is roughly truth equational. Finally, by Theorem 830, $\mathcal{I}$ is family c-reflective and, by Proposition 243, it is family reflective and, hence, family injective. Thus, it must have theorems. ■

Our next goal is to prove an analog of the characterization theorem, Theorem 839, of truth equationality in terms of the solubility of the Suszko core for rough truth equationality.

Rough truth equationality allows the following expression for all theory families with nonempty components, forming an analog of Proposition 829.

Proposition 1108 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following conditions are equivalent:*

- (i) $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b ;
- (ii) For all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{\tau^b}(\Omega(T)) = \widetilde{T}$;
- (iii) For all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{\tau^b}(\Omega(T)) = T$.

Proof:

- (i) $\Rightarrow$ (ii) Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in \overleftarrow{\tau^b}_{\Sigma}(\Omega(T)) & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{definition}) \\ & \text{ iff } \phi \in \widetilde{T}_{\Sigma}. \quad (\text{rough truth equationality}) \end{aligned}$$

- (ii) $\Rightarrow$ (iii) Suppose Condition (ii) holds. Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Since $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $T = \widetilde{T}$, whence, by hypothesis, $T = \overleftarrow{\tau^b}(\Omega(T))$.

- (iii) $\Rightarrow$ (i) If, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $T = \overleftarrow{\tau^b}(\Omega(T))$, then, by Proposition 1106, $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b .

■

Recall from Chapter 6 that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *roughly family c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \tilde{T} \leq \tilde{T'}.$$

We are now able to show that rough truth equationality implies rough family c-reflectivity. This is an analog of Theorem 830.

Theorem 1109 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly truth equational, then it is roughly family c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} \tilde{T} &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 1108}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis}) \\ &= \tilde{T'}. \quad (\text{Proposition 1108}) \end{aligned}$$

Thus, $\mathcal{I}$ is roughly family c-reflective. ■

In the context of rough truth equationality, the notion paralleling the Suszko core is the *rough Suszko core*, a modification of the original which is defined, quite naturally, by circumventing theory families with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **rough Suszko core** $S^{\mathcal{I}^\sharp}$ of $\mathcal{I}$ is the collection

$$S^{\mathcal{I}^\sharp} = \{\sigma^b \in N^b : (\forall T \in \text{ThFam}(\mathcal{I}))(\sigma^b[\tilde{T}] \leq \tilde{\Omega}^{\mathcal{I}}(\tilde{T}))\}.$$

As before, an alternative characterization avoids $\sim$ at the expense of restricting quantification over $\text{ThFam}^\sharp(\mathcal{I})$.

Proposition 1110 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$S^{\mathcal{I}^\sharp} = \{\sigma^b \in N^b : (\forall T \in \text{ThFam}^\sharp(\mathcal{I}))(\sigma^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T))\}.$$

Proof: Inside this proof we set

$$M^{\mathcal{I}} = \{\sigma^b \in N^b : (\forall T \in \text{ThFam}^\sharp(\mathcal{I}))(\sigma^b[T] \leq \tilde{\Omega}^{\mathcal{I}}(T))\}.$$

Our goal is to show that $S^{\mathcal{I}^\sharp} = M^{\mathcal{I}}$. Suppose, first, that $\sigma^b \in S^{\mathcal{I}^\sharp}$ and let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$. Since

$T \in \text{ThFam}^{\sharp}(\mathcal{I})$, we get $\tilde{T} = T$. Hence, by hypothesis, $\phi \in \tilde{T}_{\Sigma}$. Thus, since $\sigma^b \in S^{\mathcal{I}^{\sharp}}$, we get

$$\sigma_{\Sigma}^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(\tilde{T}) = \tilde{\Omega}^{\mathcal{I}}(T).$$

This proves that $\sigma^b \in M^{\mathcal{I}}$. Assume, conversely, that $\sigma^b \in M^{\mathcal{I}}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in \tilde{T}_{\Sigma}$. Since $\tilde{T} \in \text{ThFam}^{\sharp}(\mathcal{I})$ and $\sigma^b \in M^{\mathcal{I}}$, we get $\sigma_{\Sigma}^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(\tilde{T})$, whence, $\sigma^b \in S^{\mathcal{I}^{\sharp}}$. This proves that $S^{\mathcal{I}^{\sharp}} = M^{\mathcal{I}}$. ■

From the definition, it is not difficult to see that any theory family T with all its components nonempty is always included in $\overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(T))$. This forms an analog in the rough context of Proposition 833.

Proposition 1111 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$,*

$$T \leq \overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(T)).$$

Proof: Suppose $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_{\Sigma}$, and $\sigma^b \in S^{\mathcal{I}^{\sharp}}$. Then, by Proposition 1110, $\sigma_{\Sigma}^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)$. Hence, $S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T)$. By definition, then, $\phi \in \overleftarrow{S}^{\mathcal{I}^{\sharp}}_{\Sigma}(\Omega(T))$. Since Σ and $\phi \in T_{\Sigma}$ were arbitrary, we conclude that $T \leq \overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, we say that the rough Suszko core of $\mathcal{I}$ is *soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The rough Suszko core $S^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is said to be **soluble** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_{\Sigma}.$$

An alternative way to express solubility is to again expand the view to all theory families at the balancing expense of adding rough equivalence representatives.

Lemma 1112 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $S^{\mathcal{I}^{\sharp}}$ is soluble if and only if, for all $T \in \text{ThFam}(\mathcal{I})$,*

$$\tilde{T} = \overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(T)).$$

Proof: $S^{\mathcal{I}^{\sharp}}$ is soluble if and only if, by definition and Proposition 1111, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $T = \overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(T))$, if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\tilde{T} = \overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(\tilde{T}))$, if and only if, by Proposition 369, for all $T \in \text{ThFam}(\mathcal{I})$, $\tilde{T} = \overleftarrow{S}^{\mathcal{I}^{\sharp}}(\Omega(T))$. ■

As was the case with truth equationality (see Lemma 836), it turns out that, if a given π -institution is roughly truth equational, then any collection of witnessing equations must be included in the rough Suszko core of $\mathcal{I}$. Differently put, in case of rough truth equationality, the rough Suszko core is a candidate for the largest set of witnessing equations.

Lemma 1113 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , then $\tau^b \subseteq S^{\mathcal{I}^\sharp}$.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$. Then, for all $T \leq T' \in \text{ThFam}(\mathcal{I})$, we have $T' \in \text{ThFam}^\sharp(\mathcal{I})$ and $\phi \in T'_\Sigma$. Thus, by rough truth equationality, and Proposition 1106, $\tau_\Sigma^b[\phi] \leq \Omega(T')$. Since T' , with the postulated properties was arbitrary,

$$\tau_\Sigma^b[\phi] \leq \bigcap \{ \Omega(T') : T \leq T' \} = \tilde{\Omega}^{\mathcal{I}}(T).$$

We conclude, using Proposition 1110, that $\tau^b \subseteq S^{\mathcal{I}^\sharp}$. ■

We are now ready to prove the equivalence between rough truth equationality and the solubility of the rough Suszko core. In the next theorem, we show that truth equationality implies the solubility of the rough Suszko core. This forms a rough analog of Theorem 837.

Theorem 1114 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly truth equational, then $S^{\mathcal{I}^\sharp}$ is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T)$. Then, by rough truth equationality and Lemma 1113, $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Again, using rough truth equationality and Proposition 1106, we conclude that $\phi \in T_\Sigma$. This shows that $S^{\mathcal{I}^\sharp}$ is soluble. ■

Conversely, in a rough analog of Theorem 838, we show that the solubility of the rough Suszko core of a π -institution implies rough truth equationality.

Theorem 1115 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^{\mathcal{I}^\sharp}$ is soluble, then $\mathcal{I}$ is roughly truth equational, with witnessing equations $S^{\mathcal{I}^\sharp}$.*

Proof: Assume $S^{\mathcal{I}^\sharp}$ is soluble and let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. By Proposition 1106, it suffices to show that

$$\phi \in T_\Sigma \quad \text{iff} \quad S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T).$$

If $\phi \in T_\Sigma$, then, by Proposition 1111, $\phi \in \overleftarrow{S^{\mathcal{I}^\sharp}}_\Sigma(\Omega(T))$, i.e., $S^{\mathcal{I}^\sharp}_\Sigma[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the solubility of $S^{\mathcal{I}^\sharp}$. Thus, $\mathcal{I}$ is roughly truth equational, with witnessing equations $S^{\mathcal{I}^\sharp}$. ■

Theorems 1114 and 1115 provide the first characterization of rough truth equationality in terms of the solubility of the rough Suszko core. This parallels Theorem 839, which asserts a similar characterization for truth equationality in terms of the solubility of the Suszko core of a π -institution.

$$\mathcal{I} \text{ Roughly Truth Equational} \longleftrightarrow S^{\mathcal{I}^\sharp} \text{ Soluble}$$

Theorem 1116 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational if and only if $S^{\mathcal{I}^\sharp}$ is soluble.*

Proof: The “if” is by Theorem 1115. The “only if” by Theorem 1114. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the rough Suszko core $S^{\mathcal{I}^\sharp}$ of $\mathcal{I}$ **roughly defines theory families** if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$,

$$T = \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T)).$$

Another characterization of rough truth equationality, along the lines of Theorem 841, asserts that it is equivalent to the rough definability of theory families by the rough Suszko core.

$$\begin{aligned} \mathcal{I} \text{ Roughly Truth Equational} \\ \longleftrightarrow S^{\mathcal{I}^\sharp} \text{ Roughly Defines Theory Families} \end{aligned}$$

Theorem 1117 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational if and only if $S^{\mathcal{I}^\sharp}$ roughly defines theory families in $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}$ is roughly truth equational. By Theorem 1116, $S^{\mathcal{I}^\sharp}$ is soluble. Hence, by definition, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T)) \leq T$. Since, by Proposition 1111, the reverse always holds, we get, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $T = \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T))$. Thus, $S^{\mathcal{I}^\sharp}$ roughly defines theory families in $\mathcal{I}$. Conversely, if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $T = \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T))$, then $S^{\mathcal{I}^\sharp}$ is soluble and, therefore, by Theorem 1116, $\mathcal{I}$ is roughly truth equational. ■

We embark, next, in the process of establishing a connection between rough truth equationality and rough family c-reflectivity by means of the Suszko operator. We start by showing that, in every π -institution $\mathcal{I}$, $T \leq \overleftarrow{S^{\mathcal{I}^\sharp}}(\Omega(T))$ actually holds for every theory family of $\mathcal{I}$ and not only for those theory families in $\text{ThFam}^\sharp(\mathcal{I})$.

Lemma 1118 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\phi \in T_\Sigma \quad \text{implies} \quad S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T).$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in T_\Sigma & \text{ implies } \phi \in \tilde{T}_\Sigma \quad (T \leq \tilde{T}) \\ & \text{ implies } S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(\tilde{T}) \quad (\text{definition of } S^{\mathcal{I}^\sharp}) \\ & \text{ implies } S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(\tilde{T}) \quad (\tilde{\Omega}^{\mathcal{I}}(\tilde{T}) \leq \Omega(\tilde{T})) \\ & \text{ iff } S_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T). \quad (\text{Proposition 369}) \end{aligned}$$

This establishes the displayed implication. ■

In the sequel, in dealing with intersections of Leibniz congruence systems, as, e.g., when computing a Suszko congruence system, we shall have the need to switch between arbitrary collections of theory families and collections of theory families having all components nonempty. In all those situations, the following straightforward technical lemma is quite useful.

Lemma 1119 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $X \in \text{SenFam}(\mathbf{F})$ and $\theta \in \text{SenFam}(\mathbf{F}^2)$.*

- (a) $\{\Omega(T) : X \leq T \in \text{ThFam}(\mathcal{I})\} = \{\Omega(T) : X \leq T \in \text{ThFam}^\sharp(\mathcal{I})\};$
- (b) $\{\Omega(T) : X \leq T \in \text{ThFam}(\mathcal{I}) \text{ and } \theta \leq \Omega(T)\} = \{\Omega(T) : X \leq T \in \text{ThFam}^\sharp(\mathcal{I}) \text{ and } \theta \leq \Omega(T)\}.$

Proof:

- (a) Since $\text{ThFam}^\sharp(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I})$, it is clear that

$$\{\Omega(T) : X \leq T \in \text{ThFam}^\sharp(\mathcal{I})\} \subseteq \{\Omega(T) : X \leq T \in \text{ThFam}(\mathcal{I})\}.$$

To prove the reverse inclusion, let $T \in \text{ThFam}(\mathcal{I})$, such that $X \leq T$. Consider $\tilde{T} \in \text{ThFam}^\sharp(\mathcal{I})$. We get $X \leq T \leq \tilde{T}$ and, moreover, by Proposition 369, $\Omega(\tilde{T}) = \Omega(T)$. This proves that $\{\Omega(T) : X \leq T \in \text{ThFam}(\mathcal{I})\} \subseteq \{\Omega(T) : X \leq T \in \text{ThFam}^\sharp(\mathcal{I})\}.$

- (b) As in Part (a), the right-to-left inclusion is obvious. For the reverse, consider $T \in \text{ThFam}(\mathcal{I})$, such that $X \leq T$ and $\theta \leq \Omega(T)$. Then, again, $\tilde{T} \in \text{ThFam}^\sharp(\mathcal{I})$, such that both $X \leq T \leq \tilde{T}$ and $\theta \leq \Omega(T) = \Omega(\tilde{T})$. This shows that the left-to-right inclusion also holds. ■

As a corollary, we obtain, for instance, an alternative expression for the Suszko congruence system associated with a given theory family of a π -institution $\mathcal{I}$.

Corollary 1120 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$,*

$$\tilde{\Omega}^{\mathcal{I}}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThFam}^{\sharp}(\mathcal{I}) \}.$$

Proof: Immediate by the definition of $\tilde{\Omega}^{\mathcal{I}}$ and Lemma 1119. ■

Based on Lemma 1118, we may show that, for every theory family T , $T \leq S^{\mathcal{I}^{\sharp}}(\tilde{\Omega}^{\mathcal{I}}(T))$.

Proposition 1121 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\phi \in T_{\Sigma} \quad \text{implies} \quad S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T).$$

Proof: Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in T_{\Sigma} & \text{ implies } \phi \in T'_{\Sigma}, \text{ for all } T \leq T' \in \text{ThFam}(\mathcal{I}) \\ & \text{ implies } S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T'), \text{ for all } T \leq T' \in \text{ThFam}(\mathcal{I}) \\ & \quad \text{(by Lemma 1118)} \\ & \text{ iff } S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T). \quad \text{(definition of } \tilde{\Omega}^{\mathcal{I}} \text{)} \end{aligned}$$

■

In analogy with the case of rough truth equationality, we may introduce the notion of *adequacy* of the rough Suszko core, which will help in characterizing the relationship between rough truth equationality and rough c-reflectivity. The following proposition, a rough analog of Proposition 842, partially justifies the notion of adequacy that will follow.

Proposition 1122 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\begin{aligned} \phi \in T_{\Sigma} & \text{ implies } S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \quad \text{(Proposition 1121)} \\ & \text{ implies } S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T). \quad (\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{aligned}$$

Hence,

$$\begin{aligned} \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \} & \leq \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \} \\ & \leq \bigcap \{ \Omega(T) : \phi \in T_{\Sigma} \} \\ & = \tilde{\Omega}^{\mathcal{I}}(C(\phi)). \end{aligned}$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1122 holds, then we say that the rough Suszko core of $\mathcal{I}$ is *adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the rough Suszko core $S^{\mathcal{I}^\sharp}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \bigcap \{ \Omega(T) : S_{\Sigma}^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \}.$$

We can show right away that solubility of the rough Suszko core implies adequacy.

Corollary 1123 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^{\mathcal{I}^\sharp}$ is soluble, then it is adequate.*

Proof: Suppose $S^{\mathcal{I}^\sharp}$ is soluble and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(C(\phi)) &= \bigcap \{ \Omega(T) : T \in \text{ThFam}(\mathcal{I}) \text{ and } \phi \in T_{\Sigma} \} \\ &\quad (\text{definition of } \tilde{\Omega}^{\mathcal{I}}) \\ &= \bigcap \{ \Omega(T) : T \in \text{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \phi \in T_{\Sigma} \} \\ &\quad (\text{Lemma 1119}) \\ &= \bigcap \{ \Omega(T) : T \in \text{ThFam}^{\sharp}(\mathcal{I}) \text{ and } S_{\Sigma}^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \} \\ &\quad (\text{solubility of } S^{\mathcal{I}^\sharp}) \\ &= \bigcap \{ \Omega(T) : T \in \text{ThFam}(\mathcal{I}) \text{ and } S_{\Sigma}^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \}. \\ &\quad (\text{Lemma 1119}) \end{aligned}$$

Thus, $S^{\mathcal{I}^\sharp}$ is adequate. ■

We prove, next, the converse of Corollary 1123, under the additional assumption that the π -institution $\mathcal{I}$ under consideration is roughly family c-reflective. This constitutes an analog of Proposition 847.

Proposition 1124 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a roughly family c-reflective π -institution based on $\mathbf{F}$. If $S^{\mathcal{I}^\sharp}$ is adequate, then it is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly family c-reflective and $S^{\mathcal{I}^\sharp}$ is adequate. Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $S_{\Sigma}^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T)$. By the adequacy of $S^{\mathcal{I}^\sharp}$, we get that $\tilde{\Omega}^{\mathcal{I}}(C(\phi)) \leq \Omega(T)$. By Lemma 1119,

$$\bigcap \{ \Omega(T) : T \in \text{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \phi \in T_{\Sigma} \} \leq \Omega(T).$$

By rough family c-reflectivity, $\bigcap \{ T \in \text{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \phi \in T_{\Sigma} \} \leq T$. Hence, $\phi \in T_{\Sigma}$. We conclude that $S^{\mathcal{I}^\sharp}$ is soluble. ■

We are now in a position to prove the main characterization theorem relating rough truth equationality with rough family c-reflectivity, an analog

of Theorem 848, which characterized truth equationality in terms of family c-reflectivity and the adequacy of the Suszko core.

$$\begin{aligned}
 \text{Rough Truth Equationality} &= S^{\mathcal{I}\sharp} \text{ Soluble} \\
 &= S^{\mathcal{I}\sharp} \text{ Roughly Defines Theory Families} \\
 &= \text{Rough Family c-Reflectivity} \\
 &\quad + S^{\mathcal{I}\sharp} \text{ Adequate}
 \end{aligned}$$

Theorem 1125 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational if and only if it is roughly family c-reflective and has an adequate rough Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly truth equational. By Theorem 1109, it is roughly family c-reflective. By Theorem 1114, its rough Suszko core is soluble. Thus, by Corollary 1123, its rough Suszko core is also adequate.

Assume, conversely, that $\mathcal{I}$ is roughly family c-reflective and has an adequate rough Suszko core. Then, by Proposition 1124, its rough Suszko core is also soluble. Hence, by Theorem 1116, $\mathcal{I}$ is roughly truth equational. ■

Even though Theorem 848 formed the inspiration for the formulation of Theorem 1125, we show that it can be obtained as a corollary of the latter. This also exhibits the close connection between the two results which should have been anticipated, given the fact that the work done here is intended to mimic the former, while circumventing potential obstacles due to the absence of theorems.

Corollary 1126 (Theorem 848) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is truth equational if and only if it is family c-reflective and has an adequate Suszko core.*

Proof: $\mathcal{I}$ is truth equational if and only if, by Corollary 1107, it is roughly truth equational and has theorems if and only if, by Theorem 1125, it is roughly family c-reflective, has theorems and has an adequate rough Suszko core if and only if, by Theorem 468 and the definitions of the Suszko core, the rough Suszko core and their adequacy properties, $\mathcal{I}$ is family c-reflective and its Suszko core is adequate. ■

We close the section by looking at a couple of results that may be perceived either as alternative characterizations of rough truth equationality, involving arbitrary $\mathbf{F}$ -algebraic systems, or as transfer theorems.

Theorem 1127 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,*

$$\phi \in \tilde{T}_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is roughly truth equational.

Suppose, conversely, that $\mathcal{I}$ is roughly truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \alpha_{\Sigma}(\phi) \in \widetilde{T}_{F(\Sigma)} & \text{ iff } \phi \in \alpha_{\Sigma}^{-1}(\widetilde{T}_{F(\Sigma)}) \\ & \text{ iff } \phi \in \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}) \quad (\text{Theorem 377}) \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \Omega(\alpha^{-1}(T)) \quad (\text{hypothesis}) \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad (\text{Proposition 24}) \\ & \text{ iff } \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_{\Sigma}(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\text{Lemma 95}) \end{aligned}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. $\blacksquare$

In analogy with the notation $\text{ThFam}^{\mathcal{I}}(\mathcal{I})$, we introduce the following for filter families over arbitrary $\mathbf{F}$ -algebraic systems all of whose components are nonempty.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system. Define $\text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A})$ to be the collection of all $\mathcal{I}$ -filter families T on $\mathcal{A}$, such that $T_{\Sigma} \neq \emptyset$, for all $\Sigma \in |\mathbf{Sign}|$:

$$\text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A}) = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : (\forall \Sigma \in |\mathbf{Sign}|)(T_{\Sigma} \neq \emptyset)\}.$$

We now get immediately the following corollary.

Corollary 1128 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly truth equational, with witnessing equations τ^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,*

$$\phi \in T_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: Suppose that $\mathcal{I}$ is roughly truth equational. Then, if $\mathcal{A}$ is an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A})$, we get

$$\begin{aligned} T &= \widetilde{T} \quad (T \in \text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A})) \\ &= \overleftarrow{\tau^{\mathcal{A}}}(\Omega^{\mathcal{A}}(T)). \quad (\text{Theorem 1127}) \end{aligned}$$

Suppose, conversely, that the displayed condition holds. Then, if $\mathcal{A}$ is an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get, taking into account that $\widetilde{T} \in \text{FiFam}^{\mathcal{I}^{\sharp}}(\mathcal{A})$,

$$\begin{aligned} \widetilde{T} &= \overleftarrow{\tau^{\mathcal{A}}}(\Omega^{\mathcal{A}}(\widetilde{T})) \quad (\text{hypothesis}) \\ &= \overleftarrow{\tau^{\mathcal{A}}}(\Omega^{\mathcal{A}}(T)). \quad (\text{Proposition 369}) \end{aligned}$$

This establishes the claimed equivalence. $\blacksquare$

14.3 Rough Left Truth Equationality

We now turn to *rough left truth equationality*. As the terminology suggests:

- It is in the same relation to rough left c-reflectivity as rough truth equationality is to rough c-reflectivity.
- It is in the same relation to rough truth equationality as left truth equationality is to truth equationality.

Roughly speaking (in both senses), rough left truth equationality is defined analogously to left truth equationality, but it is applied to rough representatives of theory families so as to avoid theory families with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **roughly left truth equational** if there exists $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \widetilde{\overleftarrow{T}}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

The collection $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b is referred to as a set of **witnessing equations** (of/for the rough left truth equationality of $\mathcal{I}$).

The following relationship between rough left truth equationality and left truth equationality, an analog of the relationship between rough truth equationality and truth equationality, presented in Corollary 1107, holds.

Proposition 1129 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if it is roughly left truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b , and that it has theorems. Availability of theorems implies that $\text{ThFam}^{\sharp}(\mathcal{I}) = \text{ThFam}(\mathcal{I})$. Thus, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ if and only if $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is left truth equational, with the same witnessing equations τ^b .

Assume, conversely, that $\mathcal{I}$ is left truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \widetilde{\overleftarrow{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. This clearly implies that $\mathcal{I}$ has theorems, since,

otherwise, given that $\Omega(\overline{\emptyset}) = \nabla^{\mathbf{F}} = \Omega(\text{SEN}^b)$, we would get $\text{SEN}^b = \overleftarrow{\text{SEN}^b} = \overleftarrow{\overline{\emptyset}} = \overline{\emptyset}$, a contradiction. Moreover, due to the availability of theorems, we get, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{\overline{T}}_\Sigma$ if and only if $\phi \in \overleftarrow{T}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is roughly left truth equational. ■

Our next goal is to prove an analog of the characterization theorem, Theorem 861, of left truth equationality in terms of the left solubility of the left Suszko core for rough left truth equationality.

Rough left truth equationality allows an expression for $\overleftarrow{\overline{T}}$, for all theory families T , in terms of the Leibniz congruence system of T . The following proposition forms an analog of Proposition 1108.

Proposition 1130 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{\overline{T}} = \overleftarrow{\tau^b}(\Omega(T))$.*

Proof: $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{\overline{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$, if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{\overline{T}} = \overleftarrow{\tau^b}(\Omega(T))$. ■

Recall from Chapter 6 that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *roughly left c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{\overline{T}} \leq \overleftarrow{\overline{T'}}.$$

We are now able to show that rough left truth equationality implies rough left c-reflectivity. This is an analog of Theorem 1109.

Theorem 1131 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly left truth equational, then it is roughly left c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} \overleftarrow{\overline{T}} &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 1130}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis}) \\ &= \overleftarrow{\overline{T'}}. \quad (\text{Proposition 1130}) \end{aligned}$$

Thus, $\mathcal{I}$ is roughly left c-reflective. ■

In the context of rough left truth equationality, the notion paralleling the left Suszko core is the *rough left Suszko core*, a modification of the original, which is defined below.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **rough left Suszko core** $\tilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ is the collection

$$\begin{aligned} \tilde{L}^{\mathcal{I}} = \{ \sigma^b \in N^b : & (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \mathbf{SEN}^b(\Sigma)) \\ & (\sigma_{\Sigma}^b[\phi] \leq \cap \{ \Omega(T) : \phi \in \tilde{T}_{\Sigma} \}) \}. \end{aligned}$$

From the definition, it is not difficult to see that, for any theory family T , $\tilde{T}$ is always included in $\tilde{L}^{\mathcal{I}}(\Omega(T))$. This forms an analog in the rough left context of Proposition 1111.

Proposition 1132 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}(\mathcal{I})$,*

$$\tilde{T} \leq \tilde{L}^{\mathcal{I}}(\Omega(T)).$$

Proof: Suppose $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in \tilde{T}_{\Sigma}$, and $\sigma^b \in \tilde{L}^{\mathcal{I}}$. Then, by the definition of $\tilde{L}^{\mathcal{I}}$, $\sigma_{\Sigma}^b[\phi] \leq \Omega(T)$. Hence, $\tilde{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Thus, by definition of $\tilde{L}^{\mathcal{I}}(\Omega(T))$, $\phi \in \tilde{L}_{\Sigma}^{\mathcal{I}}(\Omega(T))$. Since Σ and $\phi \in \tilde{T}_{\Sigma}$ were arbitrary, we conclude that $\tilde{T} \leq \tilde{L}^{\mathcal{I}}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \text{ThFam}(\mathcal{I})$, we say that the rough left Suszko core of $\mathcal{I}$ is *left soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The rough left Suszko core $\tilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ is said to be **left soluble** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\tilde{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \tilde{T}_{\Sigma}.$$

As was the case with rough truth equationality (see Lemma 1113), it turns out that, if a given π -institution is roughly left truth equational, then any collection of witnessing equations must be included in the rough left Suszko core of $\mathcal{I}$. In other words, in case of rough left truth equationality, the rough left Suszko core forms a candidate for the largest collection of witnessing equations.

Lemma 1133 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b , then $\tau^b \subseteq \tilde{L}^{\mathcal{I}}$.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in \widetilde{\widetilde{T}}_\Sigma$. Then, by rough left truth equationality, $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Since T was arbitrary,

$$\tau_\Sigma^b[\phi] \leq \bigcap \{ \Omega(T) : \phi \in \widetilde{\widetilde{T}}_\Sigma \}.$$

Hence, since $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$ were arbitrary, we conclude that $\tau^b \subseteq \widetilde{\widetilde{L}}^\mathcal{I}$. ■

We are now ready to prove the equivalence between rough left truth equationality and the left solubility of the rough left Suszko core. In the next theorem, we show that rough left truth equationality implies the left solubility of the rough left Suszko core. This forms an analog of Theorem 1114.

Theorem 1134 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly left truth equational, then $\widetilde{\widetilde{L}}^\mathcal{I}$ is left soluble.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\widetilde{\widetilde{L}}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T)$. Then, by rough left truth equationality and Lemma 1133, $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Again, using rough left truth equationality, we conclude that $\phi \in \widetilde{\widetilde{T}}_\Sigma$. This shows that $\widetilde{\widetilde{L}}^\mathcal{I}$ is left soluble. ■

Conversely, in an analog of Theorem 1115, we show that the left solubility of the rough left Suszko core of a π -institution implies rough left truth equationality.

Theorem 1135 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\widetilde{\widetilde{L}}^\mathcal{I}$ is left soluble, then $\mathcal{I}$ is roughly left truth equational, with witnessing equations $\widetilde{\widetilde{L}}^\mathcal{I}$.*

Proof: Assume $\widetilde{\widetilde{L}}^\mathcal{I}$ is left soluble and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. We must show that

$$\phi \in \widetilde{\widetilde{T}}_\Sigma \quad \text{iff} \quad \widetilde{\widetilde{L}}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T).$$

If $\phi \in \widetilde{\widetilde{T}}_\Sigma$, then, by Proposition ??, $\phi \in \widetilde{\widetilde{L}}_\Sigma^\mathcal{I}(\Omega(T))$, i.e., $\widetilde{\widetilde{L}}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated left solubility of $\widetilde{\widetilde{L}}^\mathcal{I}$. Thus, $\mathcal{I}$ is indeed roughly left truth equational, with witnessing equations $\widetilde{\widetilde{L}}^\mathcal{I}$. ■

Theorems 1134 and 1135 provide the first characterization of rough left truth equationality in terms of the left solubility of the rough left Suszko

core. This parallels Theorem 1116, which asserted a similar characterization for rough truth equationality in terms of the solubility of the rough Suszko core of a π -institution.

$$\mathcal{I} \text{ Roughly Left Truth Equational} \longleftrightarrow \widetilde{L}^{\mathcal{I}} \text{ Left Soluble}$$

Theorem 1136 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly left truth equational if and only if $\widetilde{L}^{\mathcal{I}}$ is left soluble.*

Proof: The “if” is by Theorem 1135. The “only if” by Theorem 1134. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the rough left Suszko core $\widetilde{L}^{\mathcal{I}}$ of $\mathcal{I}$ **roughly defines theory families up to arrow** if, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\widetilde{\widetilde{T}} = \widetilde{\widetilde{L}^{\mathcal{I}}}(\Omega(T)).$$

Another characterization of rough left truth equationality, along the lines of Theorem 1117, asserts that it is equivalent to the rough definability up to arrow of the theory families by the rough left Suszko core.

$$\begin{aligned} \mathcal{I} \text{ Roughly Left Truth Equational} \\ \longleftrightarrow \widetilde{L}^{\mathcal{I}} \text{ Roughly Defines Theory Families Up to Arrow} \end{aligned}$$

Theorem 1137 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly left truth equational if and only if $\widetilde{L}^{\mathcal{I}}$ roughly defines theory families in $\mathcal{I}$ up to arrow.*

Proof: Suppose $\mathcal{I}$ is roughly left truth equational. By Theorem 1134, $\widetilde{L}^{\mathcal{I}}$ is left soluble. Hence, by definition, for all $T \in \text{ThFam}(\mathcal{I})$, $\widetilde{\widetilde{L}^{\mathcal{I}}}(\Omega(T)) \leq \widetilde{\widetilde{T}}$. Since, by Proposition 1132, the reverse inclusion always holds, we get, for all $T \in \text{ThFam}(\mathcal{I})$, $\widetilde{\widetilde{T}} = \widetilde{\widetilde{L}^{\mathcal{I}}}(\Omega(T))$. Thus, $\widetilde{L}^{\mathcal{I}}$ roughly defines theory families in $\mathcal{I}$ up to arrow. Conversely, if, for all $T \in \text{ThFam}(\mathcal{I})$, $\widetilde{\widetilde{T}} = \widetilde{\widetilde{L}^{\mathcal{I}}}(\Omega(T))$, then $\widetilde{L}^{\mathcal{I}}$ is left soluble and, therefore, by Theorem 1135, $\mathcal{I}$ is roughly left truth equational. ■

We establish, next, a connection between rough left truth equationality and rough left c-reflectivity by means of the rough left Suszko core. To help us in this task, in analogy with the case of rough truth equationality, we introduce the notion of *left adequacy* of the rough left Suszko core. The following proposition, a “left” analog of Proposition 1122, motivates and, in a sense, justifies, the notion of left adequacy that will follow. Its role parallels that of Proposition 1122 in motivating the definition of adequacy of the rough Suszko core.

Proposition 1138 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : \tilde{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \leq \bigcap \{ \Omega(T) : \phi \in \tilde{\tilde{T}}_\Sigma \}.$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \mathbf{ThFam}(\mathcal{I})$,

$$\phi \in \tilde{\tilde{T}}_\Sigma \text{ implies } \tilde{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T). \quad (\text{Definition of } \tilde{L}^\mathcal{I})$$

Hence,

$$\bigcap \{ \Omega(T) : \tilde{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \} \leq \bigcap \{ \Omega(T) : \phi \in \tilde{\tilde{T}}_\Sigma \}.$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1138 holds, then we say that the rough left Suszko core of $\mathcal{I}$ is *left adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the rough left Suszko core $\tilde{L}^\mathcal{I}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\bigcap \{ \Omega(T) : \phi \in \tilde{\tilde{T}}_\Sigma \} \leq \bigcap \{ \Omega(T) : \tilde{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \}.$$

We can show, in analogy with Corollary 1123, that the left solubility of the rough left Suszko core implies left adequacy.

Corollary 1139 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\tilde{L}^\mathcal{I}$ is left soluble, then it is left adequate.*

Proof: Suppose $\tilde{L}^\mathcal{I}$ is left soluble and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, by left solubility and Proposition 1132, for all $T \in \mathbf{ThFam}(\mathcal{I})$, $\phi \in \tilde{\tilde{T}}_\Sigma$ if and only if $\tilde{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T)$. Therefore,

$$\bigcap \{ \Omega(T) : \phi \in \tilde{\tilde{T}}_\Sigma \} = \bigcap \{ \Omega(T) : \tilde{L}_\Sigma^\mathcal{I}[\phi] \leq \Omega(T) \}.$$

Thus, $\tilde{L}^\mathcal{I}$ is left adequate. ■

We prove, next, the converse of Corollary 1139, under the additional assumption that the π -institution $\mathcal{I}$ under consideration is roughly left c-reflective. This constitutes an analog of Proposition 1124.

Proposition 1140 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a roughly left c-reflective π -institution based on $\mathbf{F}$. If $\tilde{L}^\mathcal{I}$ is left adequate, then it is left soluble.*

Proof: Suppose $\mathcal{I}$ is roughly left c-reflective and $\tilde{L}^{\mathcal{I}}$ is left adequate. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\tilde{L}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. By the postulated left adequacy of $\tilde{L}^{\mathcal{I}}$, we get that $\cap\{\Omega(T) : \phi \in \tilde{\tilde{T}}_{\Sigma}\} \leq \Omega(T)$. By rough left truth equationality, $\cap\{\tilde{\tilde{T}} : \phi \in \tilde{\tilde{T}}_{\Sigma}\} \leq \tilde{\tilde{T}}$. Therefore, $\phi \in \tilde{\tilde{T}}_{\Sigma}$. We conclude that $\tilde{L}^{\mathcal{I}}$ is left soluble. ■

We are now in a position to prove the main characterization theorem relating rough left truth equationality with rough left c-reflectivity, an analog of Theorem 1125, which characterized rough truth equationality in terms of rough family c-reflectivity and the adequacy of the rough Suszko core.

$$\begin{aligned}
 \text{Rough Left Truth Equationality} &= \tilde{L}^{\mathcal{I}} \text{ Left Soluble} \\
 &= \tilde{L}^{\mathcal{I}} \text{ Roughly Defines Theory} \\
 &\quad \text{Families Up to Arrow} \\
 &= \text{Rough Left c-Reflectivity} \\
 &\quad + \tilde{L}^{\mathcal{I}} \text{ Left Adequate}
 \end{aligned}$$

Theorem 1141 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly left truth equational if and only if it is roughly left c-reflective and has a left adequate rough left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly left truth equational. By Theorem 1131, it is roughly left c-reflective. By Theorem 1134, its rough left Suszko core is left soluble. Thus, by Corollary 1139, its rough left Suszko core is also left adequate.

Assume, conversely, that $\mathcal{I}$ is roughly left c-reflective and has a left adequate rough left Suszko core. Then, by Proposition 1140, its rough left Suszko core is also left soluble. Hence, by Theorem 1135, $\mathcal{I}$ is roughly left truth equational. ■

Based on Proposition 1129 and Theorem 468, it is not difficult to show, in an analog of Corollary 1126, that the characterization theorem, Theorem 871, of left truth equationality in terms of left c-reflectivity and the left adequacy of the left Suszko core, can be inferred from Theorem 1141.

Corollary 1142 (Theorem 871) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if it is left c-reflective and has a left adequate left Suszko core.*

Proof: $\mathcal{I}$ is left truth equational if and only if, by Proposition 1129, it is roughly left truth equational and has theorems, if and only if, by Theorem 1141, it is roughly left c-reflective, with a left adequate rough left Suszko core

and has theorems, if and only if, by Theorem 468 and the definitions of left Suszko core and rough left Suszko core, it is left c-reflective and has a left adequate left Suszko core. ■

We close the section by looking at a result, an analog of Theorem 1127, which may be perceived either as an alternative characterization of rough left truth equationality, involving arbitrary $\mathbf{F}$ -algebraic systems, or as a transfer theorem.

Theorem 1143 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,*

$$\phi \in \widetilde{\widetilde{T}}_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is roughly left truth equational.

Suppose, conversely, that $\mathcal{I}$ is roughly left truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \alpha_{\Sigma}(\phi) \in \widetilde{\widetilde{T}}_{F(\Sigma)} & \quad \text{iff} \quad \phi \in \alpha_{\Sigma}^{-1}(\widetilde{\widetilde{T}}_{F(\Sigma)}) \\ & \quad \text{iff} \quad \phi \in \alpha_{\Sigma}^{-1}(\widetilde{\widetilde{T}}_{F(\Sigma)}) \quad (\text{Theorem 377}) \\ & \quad \text{iff} \quad \phi \in \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}) \quad (\text{Lemma 6}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(\alpha^{-1}(T)) \quad (\text{hypothesis}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad (\text{Proposition 24}) \\ & \quad \text{iff} \quad \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_{\Sigma}(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\text{Lemma 95}) \end{aligned}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

14.4 Narrow Left Truth Equationality

We now turn to *narrow left truth equationality*. As the terminology suggests:

- It is in the same relation to narrow left c-reflectivity as rough left truth equationality is to rough left c-reflectivity;
- It is in the same relation to rough/narrow truth equationality as left truth equationality is to truth equationality.

In a nutshell, narrow left truth equationality is defined analogously to left truth equationality, but care is taken to bypass theory families with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **narrowly left truth equational** if there exists $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all $T \in \text{ThFam}^z(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

The collection $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b is referred to as a set of **witnessing equations** (of/for the narrow left truth equationality of $\mathcal{I}$).

An alternative characterization quantifies the relevant condition over all theory families, but it does so at the expense of using the rough operator on one side (and implicitly also on the other).

Lemma 1144 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly left truth equational if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\phi \in \overleftarrow{\widetilde{T}}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b , and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, since $\widetilde{T} \in \text{ThFam}^z(\mathcal{I})$, we get, by hypothesis, $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(\widetilde{T})$. Therefore, by Proposition 369, $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$.

Suppose, conversely, that the displayed equivalence holds and let $T \in \text{ThFam}^z(\mathcal{I})$. Then $\widetilde{T} = T$. Thus, by hypothesis, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{\widetilde{T}}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Therefore, $\mathcal{I}$ is narrowly left truth equational. ■

The following relationship between rough left truth equationality and left truth equationality, an analog of the relationship between rough truth equationality and truth equationality, presented in Corollary 1107, holds. Note that narrow left truth equationality is in the same relationship to left truth equationality as rough left truth equationality is to left truth equationality, as detailed in Proposition 1129.

Proposition 1145 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if it is narrowly left truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b , and that it has theorems. Availability of theorems implies that $\text{ThFam}^\sharp(\mathcal{I}) = \text{ThFam}(\mathcal{I})$. Thus, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is left truth equational, with the same witnessing equations τ^b .

Assume, conversely, that $\mathcal{I}$ is left truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{T}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. This clearly implies that $\mathcal{I}$ has theorems, since, otherwise, given that $\Omega(\overline{\emptyset}) = \nabla^{\mathbf{F}} = \Omega(\mathbf{SEN}^b)$, we would get $\mathbf{SEN}^b = \overleftarrow{\mathbf{SEN}^b} = \overleftarrow{\overline{\emptyset}} = \overline{\emptyset}$, a contradiction. Moreover, since $\text{ThFam}^\sharp(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I})$, left truth equationality implies trivially narrow left truth equationality. ■

Our next goal is to prove an analog of the characterizations, Theorem 861 and Proposition 1130, of left truth equationality and rough left truth equationality, respectively, for narrow left truth equationality.

Narrow left truth equationality allows an expression for $\overleftarrow{T}$, for all theory families T without empty components, or alternatively, for $\overleftarrow{\widetilde{T}}$, for all theory families T , in terms of the Leibniz congruence system of T . The following proposition forms an analog of Proposition 1130.

Proposition 1146 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then the following statements are equivalent:*

- (i) $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b ;
- (ii) For all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{\tau^b}(\Omega(T))$;
- (iii) For all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{\widetilde{T}} = \overleftarrow{\tau^b}(\Omega(T))$.

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b , and let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in \overleftarrow{\tau^b}_\Sigma(\Omega(T)) & \text{ iff } \tau_\Sigma^b[\phi] \leq \Omega(T) \quad (\text{definition}) \\ & \text{ iff } \phi \in \overleftarrow{T}_\Sigma. \quad (\text{hypothesis}) \end{aligned}$$

Suppose, next, that Condition (ii) holds and let $T \in \text{ThFam}(\mathcal{I})$. Then $\widetilde{T} \in \text{ThFam}^\sharp(\mathcal{I})$, whence, by hypothesis, $\overleftarrow{\widetilde{T}} = \overleftarrow{\tau^b}(\Omega(\widetilde{T})) = \overleftarrow{\tau^b}(\Omega(T))$, where the last equality holds by Proposition 369. Finally, suppose that Condition (iii)

holds and let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. Then $\tilde{T} = T$, whence, we get, by hypothesis, $\overleftarrow{T} = \overleftarrow{\tau^b}(\Omega(T))$, showing that $\mathcal{I}$ is narrowly left truth equational. ■

Recall from Chapter 6 that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *narrowly left c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}^{\sharp}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}.$$

We are now able to show that narrow left truth equationality implies narrow left c-reflectivity. This is an analog of Theorem 1131.

Theorem 1147 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly left truth equational, then it is narrowly left c-reflective.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}^{\sharp}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} \overleftarrow{T} &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 1146}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis}) \\ &= \overleftarrow{T'}. \quad (\text{Proposition 1146}) \end{aligned}$$

Thus, $\mathcal{I}$ is narrowly left c-reflective. ■

In the context of narrow left truth equationality, the notion paralleling the left Suszko core is the *narrow left Suszko core*, a modification of the original, which is defined below.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **narrow left Suszko core** $L^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is the collection

$$L^{\mathcal{I}^{\sharp}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThFam}^{\sharp}(\mathcal{I})) (\sigma^b[\overleftarrow{T}] \leq \tilde{\Omega}^{\mathcal{I}}(T)) \}.$$

From the definition, it is not difficult to see that, for any theory family T , with all components nonempty, $\overleftarrow{T}$ is always included in $\overleftarrow{L^{\mathcal{I}^{\sharp}}}(\Omega(T))$. This forms an analog in the narrow left context of Propositions 1111 and 1132.

Proposition 1148 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$,*

$$\overleftarrow{T} \leq \overleftarrow{L^{\mathcal{I}^{\sharp}}}(\Omega(T)).$$

Proof: Suppose $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in \overleftarrow{T}_{\Sigma}$, and $\sigma^b \in L^{\mathcal{I}^{\sharp}}$. Then, by the definition of $L^{\mathcal{I}^{\sharp}}$, $\sigma_{\Sigma}^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)$. Hence, $L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T)$. Thus, by definition of $\overleftarrow{L}^{\mathcal{I}^{\sharp}}(\Omega(T))$, $\phi \in \overleftarrow{L}^{\mathcal{I}^{\sharp}}_{\Sigma}(\Omega(T))$. Since Σ and $\phi \in \overleftarrow{T}_{\Sigma}$ were arbitrary, we conclude that $\overleftarrow{T} \leq \overleftarrow{L}^{\mathcal{I}^{\sharp}}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, we say that the narrow left Suszko core of $\mathcal{I}$ is *left soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The narrow left Suszko core $L^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is said to be **left soluble** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \overleftarrow{T}_{\Sigma}.$$

As was the case with rough left truth equationality (see Lemma 1133), it turns out that, if a given π -institution is narrowly left truth equational, then any collection of witnessing equations must be included in the narrow left Suszko core of $\mathcal{I}$; differently put, in case of narrow left truth equationality, the narrow left Suszko core forms a candidate for the largest collection of witnessing equations.

Lemma 1149 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b , then $\tau^b \subseteq L^{\mathcal{I}^{\sharp}}$.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in \overleftarrow{T}_{\Sigma}$. Then, for all $T \leq T' \in \text{ThFam}(\mathcal{I})$, $\phi \in \overleftarrow{T'}_{\Sigma}$, whence, by narrow left truth equationality, $\tau_{\Sigma}^b[\phi] \leq \Omega(T')$. Since T' , with the postulated properties was arbitrary,

$$\tau_{\Sigma}^b[\phi] \leq \bigcap \{ \Omega(T') : T \leq T' \in \text{ThFam}(\mathcal{I}) \} = \tilde{\Omega}^{\mathcal{I}}(T).$$

Hence, $\tau^b[\overleftarrow{T}] \leq \tilde{\Omega}^{\mathcal{I}}(T)$. Since $T \in \text{ThFam}^{\sharp}(\mathcal{I})$ was arbitrary, we conclude that $\tau^b \subseteq L^{\mathcal{I}^{\sharp}}$. ■

We are now ready to prove the equivalence between narrow left truth equationality and the left solubility of the narrow left Suszko core. In the next theorem, we show that narrow left truth equationality implies the left solubility of the narrow left Suszko core. This forms an analog of Theorem 1134.

Theorem 1150 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly left truth equational, then $L^{\mathcal{I}^{\sharp}}$ is left soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b . Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T)$. Then, by narrow left truth equationality and Lemma 1149, $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Again, using narrow left truth equationality, we conclude that $\phi \in \overleftarrow{T}_{\Sigma}$. This shows that $L^{\mathcal{I}^{\sharp}}$ is left soluble. ■

Conversely, in an analog of Theorem 1135, we show that the left solubility of the narrow left Suszko core of a π -institution implies narrow left truth equationality.

Theorem 1151 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $L^{\mathcal{I}^{\sharp}}$ is left soluble, then $\mathcal{I}$ is narrowly left truth equational, with witnessing equations $L^{\mathcal{I}^{\sharp}}$.*

Proof: Assume $L^{\mathcal{I}^{\sharp}}$ is left soluble and let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. We must show that

$$\phi \in \overleftarrow{T}_{\Sigma} \quad \text{iff} \quad L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T).$$

If $\phi \in \overleftarrow{T}_{\Sigma}$, then, by Proposition 1148, $\phi \in \overleftarrow{L^{\mathcal{I}^{\sharp}}}_{\Sigma}(\Omega(T))$, i.e., $L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated left solubility of $L^{\mathcal{I}^{\sharp}}$. Thus, $\mathcal{I}$ is indeed narrowly left truth equational, with witnessing equations $L^{\mathcal{I}^{\sharp}}$. ■

Theorems 1150 and 1151 provide the first characterization of narrow left truth equationality in terms of the left solubility of the narrow left Suszko core. This parallels Theorem 1136, which asserted a similar characterization for rough left truth equationality in terms of the left solubility of the rough left Suszko core of a π -institution.

$$\mathcal{I} \text{ Narrowly Left Truth Equational} \longleftrightarrow L^{\mathcal{I}^{\sharp}} \text{ Left Soluble}$$

Theorem 1152 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly left truth equational if and only if $L^{\mathcal{I}^{\sharp}}$ is left soluble.*

Proof: The “if” is by Theorem 1151. The “only if” by Theorem 1150. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow left Suszko core $L^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ **narrowly defines theory families up to arrow** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$,

$$\overleftarrow{T} = \overleftarrow{L^{\mathcal{I}^{\sharp}}}_{\Sigma}(\Omega(T)).$$

Another characterization of narrow left truth equationality, along the lines of Theorem 1137, asserts that it is equivalent to the narrow definability up to arrow of the theory families by the narrow left Suszko core.

$\mathcal{I}$ Narrowly Left Truth Equational

$\longleftrightarrow L^{\mathcal{I}^\sharp}$ Narrowly Defines Theory
Families Up to Arrow

Theorem 1153 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly left truth equational if and only if $L^{\mathcal{I}^\sharp}$ narrowly defines theory families in $\mathcal{I}$ up to arrow.*

Proof: Suppose $\mathcal{I}$ is narrowly left truth equational. By Theorem 1150, $L^{\mathcal{I}^\sharp}$ is left soluble. Hence, by definition, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\overleftarrow{L^{\mathcal{I}^\sharp}}(\Omega(T)) \leq \overleftarrow{T}$. Since, by Proposition 1148, the reverse always holds, we get, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^{\mathcal{I}^\sharp}}(\Omega(T))$. Thus, $L^{\mathcal{I}^\sharp}$ narrowly defines theory families in $\mathcal{I}$ up to arrow. Conversely, if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\overleftarrow{T} = \overleftarrow{L^{\mathcal{I}^\sharp}}(\Omega(T))$, then $L^{\mathcal{I}^\sharp}$ is left soluble and, therefore, by Theorem 1151, $\mathcal{I}$ is narrowly left truth equational. $\blacksquare$

We would like, next to establish a connection between narrow left truth equationality and narrow left c-reflectivity by means of the narrow left Suszko core. To accomplish this, we introduce an apparently modified version of the Suszko operator, which, however, is identical to the Suszko operator itself. This modified version is convenient for the purpose of handling proofs in a more straightforward and efficient way.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We define the **narrow Suszko operator** $\tilde{\Omega}^{\mathcal{I}^\sharp}$ by setting, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\tilde{\Omega}^{\mathcal{I}^\sharp}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThFam}^\sharp(\mathcal{I}) \}.$$

By Corollary 1120, we have, for all $T \in \text{ThFam}(\mathcal{I})$, $\tilde{\Omega}^{\mathcal{I}^\sharp}(T) = \tilde{\Omega}^{\mathcal{I}}(T)$. So this is indeed an apparent and not a substantial change and one can think, without any loss, of $\tilde{\Omega}^{\mathcal{I}^\sharp}$ as the Suszko operator.

In analogy with the case of rough truth equationality and rough left truth equationality, we may introduce the notion of *left adequacy* of the narrow left Suszko core, which will help in characterizing the relationship between narrow left truth equationality and narrow left c-reflectivity. The following proposition, a “left” analog of Proposition 1122 and an analog of Proposition 1138, justifies the notion of left adequacy that will follow.

Proposition 1154 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : L_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \} \leq \tilde{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \mathbf{ThFam}^{\sharp}(\mathcal{I})$,

$$\begin{aligned} \phi \in \overleftarrow{T}_{\Sigma} & \text{ implies } L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \quad (\text{Definition of } L^{\mathcal{I}^{\sharp}}) \\ & \text{ implies } L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T). \quad (\tilde{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)) \end{aligned}$$

Hence,

$$\begin{aligned} & \cap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \} \\ & = \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \} \\ & \leq \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \tilde{\Omega}^{\mathcal{I}}(T) \} \\ & \leq \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \phi \in \overleftarrow{T}_{\Sigma} \} \\ & = \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T \} \\ & = \tilde{\Omega}^{\mathcal{I}^{\sharp}}(C(\overrightarrow{\phi})). \end{aligned}$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1154 holds, then we say that the narrow left Suszko core of $\mathcal{I}$ is *left adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow left Suszko core $L^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is **left adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}^{\sharp}}(C(\overrightarrow{\phi})) \leq \cap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \}.$$

We can show, in analogy with Corollary 1139, that the left solubility of the narrow left Suszko core implies left adequacy.

Corollary 1155 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $L^{\mathcal{I}^{\sharp}}$ is left soluble, then it is left adequate.*

Proof: Suppose $L^{\mathcal{I}^{\sharp}}$ is left soluble and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}^{\sharp}}(C(\overrightarrow{\phi})) & = \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \overrightarrow{\phi} \leq T \} \\ & \quad (\text{definition of } \tilde{\Omega}^{\mathcal{I}^{\sharp}}) \\ & = \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } \phi \in \overleftarrow{T}_{\Sigma} \} \\ & \quad (\text{Definition of } \overrightarrow{\phi} \text{ and } \overleftarrow{T}) \\ & = \cap \{ \Omega(T) : T \in \mathbf{ThFam}^{\sharp}(\mathcal{I}) \text{ and } L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \} \\ & \quad (\text{Left solubility of } L^{\mathcal{I}^{\sharp}}) \\ & = \cap \{ \Omega(T) : L_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi] \leq \Omega(T) \}. \quad (\text{Lemma 1119}) \end{aligned}$$

Thus, $L^{\mathcal{I}^{\sharp}}$ is left adequate. ■

In order to prove a partial converse of Corollary 1155, we will employ the following characterization of narrow left c-reflectivity.

Lemma 1156 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly left c-reflective if and only if, for all $T \in \text{ThFam}(\mathcal{I})$ and all $T' \in \text{ThFam}^{\downarrow}(\mathcal{I})$,*

$$\tilde{\Omega}^{\mathcal{I}^{\downarrow}}(T) \leq \Omega(T') \quad \text{implies} \quad \overleftarrow{T} \leq \overleftarrow{T'}.$$

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left c-reflective and let $T \in \text{ThFam}(\mathcal{I})$ and $T' \in \text{ThFam}^{\downarrow}(\mathcal{I})$, such that $\tilde{\Omega}^{\mathcal{I}^{\downarrow}}(T) \leq \Omega(T')$. Then, by definition,

$$\bigcap \{ \Omega(T'') : T \leq T'' \in \text{ThFam}^{\downarrow}(\mathcal{I}) \} \leq \Omega(T').$$

Hence, by narrow left c-reflectivity, $\bigcap \{ \overleftarrow{T''} : T \leq T'' \in \text{ThFam}^{\downarrow}(\mathcal{I}) \} \leq \overleftarrow{T'}$. However, $T \leq T''$ implies that $\overleftarrow{T} \leq \overleftarrow{T''}$. Hence, we obtain $\overleftarrow{T} \leq \overleftarrow{T'}$.

Suppose, conversely, that the displayed condition in the statement holds and let $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}^{\downarrow}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, since $\mathcal{T} \subseteq \text{ThFam}^{\downarrow}(\mathcal{I})$, we get that

$$\bigcap \{ \Omega(T'') : \bigcap \mathcal{T} \leq T'' \in \text{ThFam}^{\downarrow}(\mathcal{I}) \} \leq \Omega(T').$$

By definition, then, $\tilde{\Omega}^{\mathcal{I}^{\downarrow}}(\bigcap \mathcal{T}) \leq \Omega(T')$, whence, by hypothesis, $\overleftarrow{\bigcap \mathcal{T}} \leq \overleftarrow{T'}$. Therefore, $\bigcap_{T \in \mathcal{T}} \overleftarrow{T} \leq \overleftarrow{T'}$. This shows that $\mathcal{I}$ is narrowly left c-reflective. ■

We prove, next, the converse of Corollary 1155, under the additional assumption that the π -institution $\mathcal{I}$ under consideration is narrowly left c-reflective. This constitutes an analog of Proposition 1140.

Proposition 1157 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a narrowly left c-reflective π -institution based on $\mathbf{F}$. If $L^{\mathcal{I}^{\downarrow}}$ is left adequate, then it is left soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly left c-reflective and $L^{\mathcal{I}^{\downarrow}}$ is left adequate. Let $T \in \text{ThFam}^{\downarrow}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $L_{\Sigma}^{\mathcal{I}^{\downarrow}}[\phi] \leq \Omega(T)$. By the postulated left adequacy of $L^{\mathcal{I}^{\downarrow}}$, we get that $\tilde{\Omega}^{\mathcal{I}^{\downarrow}}(C(\overrightarrow{\phi})) \leq \Omega(T)$.

By narrow left truth equationality and Lemma 1156, $\overleftarrow{C(\overrightarrow{\phi})} \leq \overleftarrow{T}$. Therefore, $\phi \in \overleftarrow{T}_{\Sigma}$. We conclude that $L^{\mathcal{I}^{\downarrow}}$ is left soluble. ■

We are now in a position to prove the main characterization theorem relating narrow left truth equationality with narrow left c-reflectivity, an analog of Theorem 1141, which characterized rough left truth equationality in terms of rough left c-reflectivity and the adequacy of the rough left Suszko core.

$$\begin{aligned} \text{Narrow Left Truth Equationality} &= L^{\mathcal{I}^{\downarrow}} \text{ Left Soluble} \\ &= L^{\mathcal{I}^{\downarrow}} \text{ Narrowly Defines Theory} \\ &\quad \text{Families Up to Arrow} \\ &= \text{Narrow Left c-Reflectivity} \\ &\quad + L^{\mathcal{I}^{\downarrow}} \text{ Left Adequate} \end{aligned}$$

Theorem 1158 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly left truth equational if and only if it is narrowly left c-reflective and has a left adequate narrow left Suszko core.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly left truth equational. By Theorem 1147, it is narrowly left c-reflective. By Theorem 1150, its narrow left Suszko core is left soluble. Thus, by Corollary 1155, its narrow left Suszko core is also left adequate.

Assume, conversely, that $\mathcal{I}$ is narrowly left c-reflective and has a left adequate narrow left Suszko core. Then, by Proposition 1157, its narrow left Suszko core is also left soluble. Hence, by Theorem 1151, $\mathcal{I}$ is narrowly left truth equational. ■

Based on Proposition 1145 and Theorem 468, it is not difficult to show, in an analog of Corollary 1142, that the characterization theorem, Theorem 871, of left truth equationality in terms of left c-reflectivity and the left adequacy of the left Suszko core, can be inferred from Theorem 1158.

Corollary 1159 (Theorem 871) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is left truth equational if and only if it is left c-reflective and has a left adequate left Suszko core.*

Proof: $\mathcal{I}$ is left truth equational if and only if, by Proposition 1145, it is narrowly left truth equational and has theorems, if and only if, by Theorem 1158, it is narrowly left c-reflective, with a left adequate narrow left Suszko core and has theorems, if and only if, by Theorem 468 and the definitions of left Suszko core and narrow left Suszko core, it is left c-reflective and has a left adequate left Suszko core. ■

We close the section by looking at a result, an analog of Theorem 1143, which may be perceived either as an alternative characterization of narrow left truth equationality, involving arbitrary $\mathbf{F}$ -algebraic systems, or as a transfer theorem.

Theorem 1160 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly left truth equational, with witnessing equations τ^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}^\sharp}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,*

$$\phi \in \overleftarrow{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is narrowly left truth equational.

Suppose, conversely, that $\mathcal{I}$ is narrowly left truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned}
 \alpha_\Sigma(\phi) \in \overleftarrow{T}_{F(\Sigma)} & \text{ iff } \phi \in \alpha_\Sigma^{-1}(\overleftarrow{T}_{F(\Sigma)}) \\
 & \text{ iff } \phi \in \overleftarrow{\alpha_\Sigma^{-1}(T_{F(\Sigma)})} \quad (\text{Lemma 6}) \\
 & \text{ iff } \tau_\Sigma^b[\phi] \leq \Omega(\alpha^{-1}(T)) \quad (\text{hypothesis}) \\
 & \text{ iff } \tau_\Sigma^b[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad (\text{Proposition 24}) \\
 & \text{ iff } \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_\Sigma(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\text{Lemma 95})
 \end{aligned}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. $\blacksquare$

14.5 Rough System Truth Equationality

We now turn to *rough system truth equationality*. As the terminology suggests:

- It is in the same relation to rough system c-reflectivity as rough left truth equationality is to rough left c-reflectivity;
- It is in the same relation to rough left truth equationality as system truth equationality is to left truth equationality.

Roughly speaking, rough system truth equationality is defined analogously to system truth equationality, but it is applied to rough representatives of theory systems so as to avoid theory systems with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **roughly system truth equational** if there exists $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

The collection $\tau^b : (\text{SEN}^b)^\omega \rightarrow (\text{SEN}^b)^2$ in N^b is referred to as a set of **witnessing equations** (of/for the rough system truth equationality of $\mathcal{I}$).

The following relationship between rough system truth equationality and system truth equationality, an analog of the relationship between rough truth equationality and truth equationality, presented in Corollary 1107, holds.

Proposition 1161 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if it is roughly system truth equational and has theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b , and that it has theorems. Availability of theorems implies that $\text{ThSys}^{\downarrow}(\mathcal{I}) = \text{ThSys}(\mathcal{I})$. Thus, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\phi \in \tilde{T}_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is system truth equational, with the same witnessing equations τ^b .

Assume, conversely, that $\mathcal{I}$ is system truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ iff $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. This clearly implies that $\mathcal{I}$ has theorems. Moreover, due to the availability of theorems, we get, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \tilde{T}_{\Sigma}$ if and only if $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is roughly system truth equational. ■

Our next goal is to prove an analog of the characterization theorem, Theorem 1136, of rough left truth equationality in terms of the left solubility of the rough left Suszko core for rough system truth equationality.

Rough system truth equationality allows an expression for $\tilde{T}$, for all theory systems T , in terms of the Leibniz congruence system of T . The following proposition forms an analog of Proposition 1130.

Proposition 1162 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tau^b}(\Omega(T))$.*

Proof: $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$, $\phi \in \tilde{T}_{\Sigma}$ iff $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$, if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tau^b}(\Omega(T))$. ■

Recall from Chapter 6 that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *roughly system c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} \tilde{T} \leq \tilde{T'}.$$

We are now able to show that rough system truth equationality implies rough system c-reflectivity. This is an analog of Theorem 1131.

Theorem 1163 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly system truth equational, then it is roughly system c-reflective.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} \tilde{T} &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 1162}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis}) \\ &= \tilde{T}'. \quad (\text{Proposition 1162}) \end{aligned}$$

Thus, $\mathcal{I}$ is roughly system c-reflective. $\blacksquare$

In the context of rough system truth equationality, the notion paralleling the rough left Suszko core is the *rough system core*, a modification of the system core, which is defined below.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **rough system core** $\tilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is the collection

$$\begin{aligned} \tilde{Z}^{\mathcal{I}} &= \{ \sigma^b \in N^b : (\forall \Sigma \in |\mathbf{Sign}^b|)(\forall \phi \in \text{SEN}^b(\Sigma)) \\ &\quad (\sigma^b_\Sigma[\phi] \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_\Sigma \}) \}. \end{aligned}$$

From the definition, it is not difficult to see that, for any theory system T , $\tilde{T}$ is always included in $\overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T))$. This forms an analog in the rough system context of Proposition 1132.

Proposition 1164 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThSys}(\mathcal{I})$,*

$$\tilde{T} \leq \overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T)).$$

Proof: Suppose $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in \tilde{T}_\Sigma$, and $\sigma^b \in \tilde{Z}^{\mathcal{I}}$. Then, by the definition of $\tilde{Z}^{\mathcal{I}}$, $\sigma^b_\Sigma[\phi] \leq \Omega(T)$. Hence, $\overleftarrow{\tilde{Z}^{\mathcal{I}}}[\phi] \leq \Omega(T)$. Thus, by definition of $\overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T))$, $\phi \in \overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T))$. Since Σ and $\phi \in \tilde{T}_\Sigma$ were arbitrary, we conclude that $\tilde{T} \leq \overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T))$. $\blacksquare$

The reverse inclusion may or may not hold. If it does, for all $T \in \text{ThSys}(\mathcal{I})$, we say that the rough system core of $\mathcal{I}$ is *soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The rough system core $\tilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is said to be **soluble** if, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\overleftarrow{\tilde{Z}^{\mathcal{I}}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in \tilde{T}_\Sigma.$$

As was the case with rough left truth equationality (see Lemma 1133), if a given π -institution is roughly system truth equational, then any collection of witnessing equations must be included in the rough system core of $\mathcal{I}$. In other words, in case of rough system truth equationality, the rough system core forms a candidate for the largest collection of witnessing equations.

Lemma 1165 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b , then $\tau^b \subseteq \tilde{Z}^{\mathcal{I}}$.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b . Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in \tilde{T}_\Sigma$. Then, by rough system truth equationality, $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Since T was arbitrary,

$$\tau_\Sigma^b[\phi] \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_\Sigma \}.$$

Hence, since $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$ were arbitrary, we conclude that $\tau^b \subseteq \tilde{Z}^{\mathcal{I}}$. ■

We are now ready to prove the equivalence between rough system truth equationality and the solubility of the rough system core. In the next theorem, we show that rough system truth equationality implies the solubility of the rough system core. This forms an analog of Theorem 1134.

Theorem 1166 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is roughly system truth equational, then $\tilde{Z}^{\mathcal{I}}$ is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b . Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\tilde{Z}_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by rough system truth equationality and Lemma 1165, $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Again, using rough system truth equationality, we conclude that $\phi \in \tilde{T}_\Sigma$. This shows that $\tilde{Z}^{\mathcal{I}}$ is soluble. ■

Conversely, in an analog of Theorem 1135, we show that the solubility of the rough system core of a π -institution implies rough system truth equationality.

Theorem 1167 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\tilde{Z}^{\mathcal{I}}$ is soluble, then $\mathcal{I}$ is roughly system truth equational, with witnessing equations $\tilde{Z}^{\mathcal{I}}$.*

Proof: Assume $\tilde{Z}^{\mathcal{I}}$ is soluble and let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. We must show that

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tilde{Z}_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T).$$

If $\phi \in \tilde{T}_\Sigma$, then, by Proposition 1164, $\phi \in \overleftarrow{\tilde{Z}^{\mathcal{I}}_\Sigma}(\Omega(T))$, i.e., $\tilde{Z}_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated solubility of $\tilde{Z}^{\mathcal{I}}$. Thus, $\mathcal{I}$ is indeed roughly system truth equational, with witnessing equations $\tilde{Z}^{\mathcal{I}}$. ■

Theorems 1166 and 1167 provide the first characterization of rough system truth equationality in terms of the solubility of the rough system core.

This parallels Theorem 1136, which asserted a similar characterization for rough left truth equationality in terms of the left solubility of the rough left Suszko core of a π -institution.

$$\mathcal{I} \text{ Roughly System Truth Equational} \longleftrightarrow \tilde{Z}^{\mathcal{I}} \text{ Soluble}$$

Theorem 1168 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly system truth equational if and only if $\tilde{Z}^{\mathcal{I}}$ is left soluble.*

Proof: The “if” is by Theorem 1167. The “only if” by Theorem 1166. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the rough system core $\tilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ **roughly defines theory systems** if, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\tilde{T} = \overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T)).$$

Another characterization of rough system truth equationality, along the lines of Theorem 1137, asserts that it is equivalent to the rough definability of the theory systems by the rough system core.

$$\begin{aligned} \mathcal{I} \text{ Roughly System Truth Equational} \\ \longleftrightarrow \tilde{Z}^{\mathcal{I}} \text{ Roughly Defines Theory Systems} \end{aligned}$$

Theorem 1169 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly system truth equational if and only if $\tilde{Z}^{\mathcal{I}}$ roughly defines theory systems in $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}$ is roughly system truth equational. By Theorem 1166, $\tilde{Z}^{\mathcal{I}}$ is soluble. Hence, by definition, for all $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T)) \leq \tilde{T}$. Since, by Proposition 1164, the reverse inclusion always holds, we get, for all $T \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T))$. Thus, $\tilde{Z}^{\mathcal{I}}$ roughly defines theory systems in $\mathcal{I}$. Conversely, if, for all $T \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tilde{Z}^{\mathcal{I}}}(\Omega(T))$, then $\tilde{Z}^{\mathcal{I}}$ is soluble and, therefore, by Theorem 1167, $\mathcal{I}$ is roughly system truth equational. ■

We establish, next, a connection between rough system truth equationality and rough system c-reflectivity by means of the rough system core. In analogy with the case of rough left truth equationality, we introduce, first, the notion of *adequacy* of the rough system core. The following proposition, a system analog of Proposition 1138, motivates the notion of adequacy that will follow.

Proposition 1170 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\begin{aligned} & \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ & \leq \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_{\Sigma} \}. \end{aligned}$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\phi \in \tilde{T}_{\Sigma} \text{ implies } \tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T). \quad (\text{Definition of } \tilde{Z}^{\mathcal{I}})$$

Hence,

$$\begin{aligned} & \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \} \\ & \leq \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_{\Sigma} \}. \end{aligned}$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1170 holds, then we say that the rough system core of $\mathcal{I}$ is *adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the rough system core $\tilde{Z}^{\mathcal{I}}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} & \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_{\Sigma} \} \\ & \leq \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \end{aligned}$$

We can show, in analogy with Corollary 1139, that the solubility of the rough system core implies its adequacy.

Corollary 1171 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\tilde{Z}^{\mathcal{I}}$ is soluble, then it is adequate.*

Proof: Suppose $\tilde{Z}^{\mathcal{I}}$ is soluble and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, by solubility and Proposition 1164, for all $T \in \text{ThSys}(\mathcal{I})$, $\phi \in \tilde{T}_{\Sigma}$ if and only if $\tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Therefore,

$$\begin{aligned} & \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_{\Sigma} \} \\ & = \cap \{ \Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \end{aligned}$$

Thus, $\tilde{Z}^{\mathcal{I}}$ is adequate. ■

We prove, next, the converse of Corollary 1171, under the additional assumption that the π -institution $\mathcal{I}$ under consideration is roughly system c -reflective. This constitutes an analog of Proposition 1140.

Proposition 1172 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a roughly system c -reflective π -institution based on $\mathbf{F}$. If $\tilde{Z}^{\mathcal{I}}$ is adequate, then it is soluble.*

Proof: Suppose $\mathcal{I}$ is roughly system c-reflective and $\tilde{Z}^{\mathcal{I}}$ is adequate. Let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $\tilde{Z}_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. By the postulated adequacy of $\tilde{Z}^{\mathcal{I}}$, we get that $\bigcap \{\Omega(T) : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_{\Sigma}\} \leq \Omega(T)$. By rough system truth equationality, $\bigcap \{\tilde{T} : T \in \text{ThSys}(\mathcal{I}) \text{ and } \phi \in \tilde{T}_{\Sigma}\} \leq \tilde{T}$. Therefore, $\phi \in \tilde{T}_{\Sigma}$. We conclude that $\tilde{Z}^{\mathcal{I}}$ is soluble. ■

We are now in a position to prove the main characterization theorem relating rough system truth equationality with rough system c-reflectivity, an analog of Theorem 1141, which characterized rough left truth equationality in terms of rough left c-reflectivity and the left adequacy of the rough left Suszko core.

$$\begin{aligned}
 &\text{Rough System Truth Equationality} \\
 &= \tilde{Z}^{\mathcal{I}} \text{ Soluble} \\
 &= \tilde{Z}^{\mathcal{I}} \text{ Roughly Defines Theory Systems} \\
 &= \text{Rough System c-Reflectivity} \\
 &\quad + \tilde{Z}^{\mathcal{I}} \text{ Adequate}
 \end{aligned}$$

Theorem 1173 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly system truth equational if and only if it is roughly system c-reflective and has an adequate rough system core.*

Proof: Suppose, first, that $\mathcal{I}$ is roughly system truth equational. By Theorem 1163, it is roughly system c-reflective. By Theorem 1166, its rough system core is soluble. Thus, by Corollary 1171, its rough system core is also adequate.

Assume, conversely, that $\mathcal{I}$ is roughly system c-reflective and has an adequate rough system core. Then, by Proposition 1172, its rough system core is also soluble. Hence, by Theorem 1167, $\mathcal{I}$ is roughly system truth equational. ■

Based on Proposition 1161 and Theorem 468, it is not difficult to show, in an analog of Corollary 1142, that the characterization theorem, Theorem 889, of system truth equationality in terms of system c-reflectivity and the adequacy of the system core, can be inferred from Theorem 1173.

Corollary 1174 (Theorem 889) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if it is system c-reflective and has an adequate system core.*

Proof: $\mathcal{I}$ is system truth equational if and only if, by Proposition 1161, it is roughly system truth equational and has theorems, if and only if, by Theorem 1173, it is roughly system c-reflective, with an adequate rough system core

and has theorems, if and only if, by Theorem 468 and the definitions of system core and rough system core, it is system c-reflective and has an adequate system core. ■

We close the section by looking at a result, an analog of Theorem 1143, which may be perceived either as an alternative characterization of rough system truth equationality, involving arbitrary $\mathbf{F}$ -algebraic systems, or as a transfer theorem.

Theorem 1175 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is roughly system truth equational, with witnessing equations τ^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,*

$$\phi \in \widetilde{T}_{\Sigma} \quad \text{iff} \quad \tau_{\Sigma}^{\mathcal{A}}[\phi] \leq \Omega^{\mathcal{A}}(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is roughly system truth equational.

Suppose, conversely, that $\mathcal{I}$ is roughly system truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \alpha_{\Sigma}(\phi) \in \widetilde{T}_{F(\Sigma)} & \quad \text{iff} \quad \phi \in \alpha_{\Sigma}^{-1}(\widetilde{T}_{F(\Sigma)}) \\ & \quad \text{iff} \quad \phi \in \alpha_{\Sigma}^{-1}(T_{F(\Sigma)}) \quad (\text{Theorem 377}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \Omega(\alpha^{-1}(T)) \quad (\text{hypothesis}) \\ & \quad \text{iff} \quad \tau_{\Sigma}^b[\phi] \leq \alpha^{-1}(\Omega^{\mathcal{A}}(T)) \quad (\text{Proposition 24}) \\ & \quad \text{iff} \quad \tau_{F(\Sigma)}^{\mathcal{A}}[\alpha_{\Sigma}(\phi)] \leq \Omega^{\mathcal{A}}(T). \quad (\text{Lemma 95}) \end{aligned}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

14.6 Narrow System Truth Equationality

Finally, we discuss *narrow system truth equationality*, the weakest of all rough/narrow truth equationality conditions. As the terminology suggests:

- It is in the same relation to narrow system c-reflectivity as rough system truth equationality is to rough system c-reflectivity;
- It is in the same relation to narrow truth equationality and narrow left truth equationality as rough system truth equationality is to rough truth equationality and rough left truth equationality, respectively.

In a nutshell, narrow system truth equationality is defined analogously to system truth equationality, but care is taken to bypass theory systems with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **narrowly system truth equational** if there exists $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b , with a single distinguished argument, such that, for all $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi/\Omega_\Sigma(T) \in \tilde{T}_\Sigma/\Omega_\Sigma(T) \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}.$$

Once more, since, by Proposition 369, for every $T \in \text{ThFam}(\mathcal{I})$, $\Omega(\tilde{T}) = \Omega(T)$, $\Omega(T)$ is compatible with $\tilde{T}$ and, hence, the preceding definition makes sense. The collection $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ in N^b is referred to as a set of **witnessing equations** (of/for the narrow system truth equationality of $\mathcal{I}$).

As in Proposition 1105, we get the following alternative characterization.

Proposition 1176 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ a collection of natural transformations in N^b , with a single distinguished argument. $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\phi \in \tilde{T}_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Proof: Suppose that $\mathcal{I}$ is narrowly truth equational and let $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in \tilde{T}_\Sigma & \quad \text{iff} \quad \phi/\Omega_\Sigma(T) \in \tilde{T}_\Sigma/\Omega_\Sigma(T) \quad (\text{Proposition 369 and compatibility}) \\ & \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \quad (\text{by definition}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T). \end{aligned}$$

Suppose, conversely, that the displayed condition holds. Let $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi/\Omega_\Sigma(T) \in \tilde{T}_\Sigma/\Omega_\Sigma(T) & \quad \text{iff} \quad \phi \in \tilde{T}_\Sigma \quad (\text{Proposition 369 and compatibility}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T) \quad (\text{by hypothesis}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi]/\Omega(T) \leq \Delta^{\mathcal{F}/\Omega(T)} \\ & \quad \text{iff} \quad \tau_\Sigma^{\mathcal{F}/\Omega(T)}[\phi/\Omega_\Sigma(T)] \leq \Delta^{\mathcal{F}/\Omega(T)}. \quad (\text{definition}) \end{aligned}$$

Therefore, $\mathcal{I}$ is narrowly system truth equational. ■

It is not difficult to see that an alternative way to express narrow system truth equationality is to assert the same condition that defines system truth

equationality, excluding, however, those theory systems with at least one empty component.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 6 that we denote by $\text{ThSys}^\sharp(\mathcal{I})$ the collection of all theory systems T of $\mathcal{I}$, such that $T_\Sigma \neq \emptyset$, for all $\Sigma \in |\mathbf{Sign}^b|$:

$$\text{ThSys}^\sharp(\mathcal{I}) = \{T \in \text{ThSys}(\mathcal{I}) : (\forall \Sigma \in |\mathbf{Sign}^b|)(T_\Sigma \neq \emptyset)\}.$$

Recall, also, that, if $\mathcal{I}$ has theorems, then $\text{ThSys}^\sharp(\mathcal{I}) = \text{ThSys}(\mathcal{I})$. In particular, this is the case if $\mathcal{I}$ happens to be system truth equational.

Proposition 1177 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\tau^b : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ a collection of natural transformations in N^b , with a single distinguished argument. $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b , if and only if, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(T).$$

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b . Let $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then $\tilde{T} = T \in \text{ThSys}(\mathcal{I})$, whence, taking into account Proposition 1176, $\phi \in T_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$.

Suppose, conversely, that the displayed condition holds. Consider $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, since, by definition of $\tilde{T}$, we have $\tilde{T} \in \text{ThSys}^\sharp(\mathcal{I})$, we get, by hypothesis, $\phi \in \tilde{T}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(\tilde{T})$, whence, using Proposition 369, we conclude that $\phi \in \tilde{T}_\Sigma$ if and only if $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Therefore, $\mathcal{I}$ is narrowly system truth equational. ■

As a corollary, we obtain the following key relationship between narrow system truth equationality and system truth equationality, paralleling the one established between rough system truth equationality and system truth equationality in Corollary 1161.

Corollary 1178 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if it is narrowly system truth equational with theorems.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b , and that it has theorems. Availability of theorems implies that $\text{ThSys}^{\sharp}(\mathcal{I}) = \text{ThSys}(\mathcal{I})$. Thus, by Proposition 1177, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is system truth equational, with the same witnessing equations τ^b .

Assume, conversely, that $\mathcal{I}$ is system truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThSys}(\mathcal{I})$, and, hence, a fortiori, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in T_{\Sigma}$ if and only if $\tau_{\Sigma}^b[\phi] \leq \Omega(T)$. Hence, again by Proposition 1177, $\mathcal{I}$ is narrowly system truth equational. Finally, by Theorem 874, $\mathcal{I}$ is system c-reflective and, by Proposition 243, it is system reflective and, therefore, system injective. Thus, it must have theorems. ■

Our next goal is to prove an analog of the characterization theorem, Theorem 1168, of rough system truth equationality in terms of the solubility of the rough system core for the case of narrow system truth equationality.

Narrow system truth equationality allows the following expression for all theory systems with nonempty components, forming an analog of Proposition 1162.

Proposition 1179 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following conditions are equivalent:*

- (i) $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b ;
- (ii) For all $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{\tau^b}(\Omega(T))$;
- (iii) For all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, $T = \overleftarrow{\tau^b}(\Omega(T))$.

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b , and let $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in \overleftarrow{\tau^b}_{\Sigma}(\Omega(T)) & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \Omega(T) \quad (\text{definition}) \\ & \text{ iff } \phi \in \tilde{T}_{\Sigma}. \quad (\text{hypothesis and Proposition 1176}) \end{aligned}$$

This proves Condition (ii). If Condition (ii) holds and $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, then $\tilde{T} = T \in \text{ThSys}(\mathcal{I})$, whence, by hypothesis, $T = \tilde{T} = \overleftarrow{\tau^b}(\Omega(T))$. Thus, Condition (iii) holds. Finally, assume Condition (iii) holds. Then, by Proposition ??, $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b . ■

Recall from Chapter 6 that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}$ is called *narrowly system c-reflective* if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}^{\sharp}(\mathcal{I})$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

We are now able to show that narrow system truth equationality implies narrow system c-reflectivity. This is an analog of Theorem 1163.

Theorem 1180 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly system truth equational, then it is narrowly system c-reflective.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b . Let $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}^{\sharp}(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then we have

$$\begin{aligned} \bigcap_{T \in \mathcal{T}} T &= \bigcap_{T \in \mathcal{T}} \overleftarrow{\tau^b}(\Omega(T)) \quad (\text{Proposition 1179}) \\ &= \overleftarrow{\tau^b}(\bigcap_{T \in \mathcal{T}} \Omega(T)) \quad (\text{set theory}) \\ &\leq \overleftarrow{\tau^b}(\Omega(T')) \quad (\text{hypothesis}) \\ &= T'. \quad (\text{Proposition 1179}) \end{aligned}$$

Thus, $\mathcal{I}$ is narrowly system c-reflective. ■

In the context of narrow system truth equationality, the notion paralleling the rough system core, introduced in Section ??, is the *narrow system core*, a modification of the original definition of the system core from Chapter 11, which is defined by circumventing theory systems with empty components.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **narrow system core** $Z^{\mathcal{I}\sharp}$ of $\mathcal{I}$ is the collection

$$Z^{\mathcal{I}\sharp} = \{\sigma^b \in N^b : (\forall T \in \text{ThSys}(\mathcal{I}))(\tilde{T} \in \text{ThSys}(\mathcal{I}) \Rightarrow \sigma^b[\tilde{T}] \leq \widehat{\Omega}^{\mathcal{I}}(\tilde{T}))\}.$$

As before, an alternative characterization avoids $\sim$ at the expense of restricting quantification over $\text{ThSys}^{\sharp}(\mathcal{I})$.

Proposition 1181 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$Z^{\mathcal{I}\sharp} = \{\sigma^b \in N^b : (\forall T \in \text{ThSys}^{\sharp}(\mathcal{I}))(\sigma^b[T] \leq \widehat{\Omega}^{\mathcal{I}}(T))\}.$$

Proof: Inside this proof we set

$$M^{\mathcal{I}\sharp} = \{\sigma^b \in N^b : (\forall T \in \text{ThSys}^{\sharp}(\mathcal{I}))(\sigma^b[T] \leq \widehat{\Omega}^{\mathcal{I}}(T))\}.$$

Our goal is to show that $Z^{\mathcal{I}\sharp} = M^{\mathcal{I}\sharp}$. Suppose, first, that $\sigma^b \in Z^{\mathcal{I}\sharp}$ and let $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_{\Sigma}$. Since $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, we get $\tilde{T} = T$. Thus, on the one hand, $\tilde{T} \in \text{ThSys}(\mathcal{I})$ and, on the other, by hypothesis, $\phi \in \tilde{T}_{\Sigma}$. Thus, since $\sigma^b \in Z^{\mathcal{I}\sharp}$, we get

$$\sigma_{\Sigma}^b[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(\tilde{T}) = \widehat{\Omega}^{\mathcal{I}}(T).$$

This proves that $\sigma^b \in M^{\mathcal{I}\sharp}$. Assume, conversely, that $\sigma^b \in M^{\mathcal{I}\sharp}$ and let $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such

that $\phi \in \tilde{T}_\Sigma$. Since $\tilde{T} \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$ and $\sigma^b \in M^{\mathcal{I}^{\mathcal{I}}}$, we get $\sigma_\Sigma^b[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(\tilde{T})$, whence, $\sigma^b \in Z^{\mathcal{I}^{\mathcal{I}}}$. This proves that $Z^{\mathcal{I}^{\mathcal{I}}} = M^{\mathcal{I}^{\mathcal{I}}}$. ■

From the definition, it is not difficult to see that any theory system T with all its components nonempty is always included in $\overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(T))$. This forms an analog in the rough system context of Proposition 1164.

Proposition 1182 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$,*

$$T \leq \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(T)).$$

Proof: Suppose $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$, and $\sigma^b \in Z^{\mathcal{I}^{\mathcal{I}}}$. Then, by Proposition ??, $\sigma_\Sigma^b[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) \leq \Omega(T)$. Hence, $Z_\Sigma^{\mathcal{I}^{\mathcal{I}}}[\phi] \leq \Omega(T)$. By definition, then, $\phi \in \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}_\Sigma(\Omega(T))$. Since Σ and $\phi \in T_\Sigma$ were arbitrary, we conclude that $T \leq \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(T))$. ■

The reverse inclusion may or may not hold. If it does, for all $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, we say that the narrow system core $Z^{\mathcal{I}^{\mathcal{I}}}$ of $\mathcal{I}$ is *soluble*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The narrow system core $Z^{\mathcal{I}^{\mathcal{I}}}$ of $\mathcal{I}$ is said to be **soluble** if, for all $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$Z_\Sigma^{\mathcal{I}^{\mathcal{I}}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_\Sigma.$$

An alternative way to express solubility is to again expand the view to all theory systems, with nonempty components, at the balancing expense of adding rough equivalence representatives. We obtain, thus, an analog of Lemma 1112.

Lemma 1183 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $Z^{\mathcal{I}^{\mathcal{I}}}$ is soluble if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$,*

$$\tilde{T} = \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(T)).$$

Proof: $Z^{\mathcal{I}^{\mathcal{I}}}$ is soluble if and only if, by definition and Proposition 1182, for all $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(T))$. It is easy to see that this holds if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(\tilde{T}))$. And this is equivalent, by Proposition 369, to the statement that, for all $T \in \text{ThSys}(\mathcal{I})$, such that $\tilde{T} \in \text{ThSys}(\mathcal{I})$, $\tilde{T} = \overleftarrow{Z^{\mathcal{I}^{\mathcal{I}}}}(\Omega(T))$. ■

As was the case with rough system truth equationality (see Lemma 1165), it turns out that, if a given π -institution is narrowly system truth equational, then any collection of witnessing equations must be included in the narrow system core of $\mathcal{I}$. That is, in case of narrow system truth equationality, the narrow system core is a candidate for the largest set of witnessing equations.

Lemma 1184 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b , then $\tau^b \subseteq Z^{\mathcal{I}^\sharp}$.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b . Let $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$. Then, for all $T \leq T' \in \text{ThSys}(\mathcal{I})$, we have $T' \in \text{ThSys}^\sharp(\mathcal{I})$ and $\phi \in T'_\Sigma$. Thus, by narrow system truth equationality and Proposition 1177, $\tau_\Sigma^b[\phi] \leq \Omega(T')$. Since T' , with the postulated properties was arbitrary,

$$\tau_\Sigma^b[\phi] \leq \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}(\mathcal{I}) \} = \widehat{\Omega}^{\mathcal{I}}(T).$$

We conclude, using Proposition 1181, that $\tau^b \subseteq Z^{\mathcal{I}^\sharp}$. ■

We are now ready to prove the equivalence between narrow system truth equationality and the solubility of the narrow system core, an analog of Theorem 1168. First, we show that narrow system truth equationality implies the solubility of the narrow system core. This forms an analog of Theorem 1166.

Theorem 1185 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is narrowly system truth equational, then $Z^{\mathcal{I}^\sharp}$ is soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b . Let $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T)$. Then, by narrow system truth equationality and Lemma 1184, $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Again, using narrow system truth equationality and Proposition 1177, we conclude that $\phi \in T_\Sigma$. This shows that $Z^{\mathcal{I}^\sharp}$ is soluble. ■

Conversely, the solubility of the narrow system core of a π -institution implies narrow system truth equationality.

Theorem 1186 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $Z^{\mathcal{I}^\sharp}$ is soluble, then $\mathcal{I}$ is narrowly system truth equational, with witnessing equations $Z^{\mathcal{I}^\sharp}$.*

Proof: Assume $Z^{\mathcal{I}^\sharp}$ is soluble and let $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. By Proposition 1177, it suffices to show that

$$\phi \in T_\Sigma \quad \text{iff} \quad Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T).$$

If $\phi \in T_\Sigma$, then, by Proposition 1182, $\phi \in \overleftarrow{Z^{\mathcal{I}^\sharp}_\Sigma}(\Omega(T))$, i.e., $Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T)$. On the other hand, the reverse inclusion is guaranteed by the postulated solubility of $Z^{\mathcal{I}^\sharp}$. Thus, $\mathcal{I}$ is indeed narrowly system truth equational, with witnessing equations $Z^{\mathcal{I}^\sharp}$. ■

Theorems 1185 and 1186 provide the first characterization of narrow system truth equationality in terms of the solubility of the narrow system core. This parallels Theorem 1168, which asserted a similar characterization for rough system truth equationality in terms of the solubility of the rough system core of a π -institution.

$$\mathcal{I} \text{ Narrowly System Truth Equational} \longleftrightarrow Z^{\mathcal{I}^\sharp} \text{ Soluble}$$

Theorem 1187 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly system truth equational if and only if $Z^{\mathcal{I}^\sharp}$ is soluble.*

Proof: The “if” is by Theorem 1186. The “only if” by Theorem 1185. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow system core $Z^{\mathcal{I}^\sharp}$ of $\mathcal{I}$ **narrowly defines theory systems** if, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$,

$$T = \overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T)).$$

Another characterization of narrow system truth equationality, along the lines of Theorem 1169, asserts that it is equivalent to the narrow definability of the theory systems by the narrow system core.

$$\begin{aligned} \mathcal{I} \text{ Narrowly System Truth Equational} \\ \longleftrightarrow Z^{\mathcal{I}^\sharp} \text{ Narrowly Defines Theory Systems} \end{aligned}$$

Theorem 1188 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly system truth equational if and only if $Z^{\mathcal{I}^\sharp}$ narrowly defines theory systems in $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}$ is narrowly system truth equational. By Theorem 1185, $Z^{\mathcal{I}^\sharp}$ is soluble. Hence, by definition, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T)) \leq T$. Since, by Proposition 1182, the reverse inclusion always holds, we get, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T))$. Thus, $Z^{\mathcal{I}^\sharp}$ narrowly defines theory systems in $\mathcal{I}$. Conversely, if, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $T = \overleftarrow{Z^{\mathcal{I}^\sharp}}(\Omega(T))$, then $Z^{\mathcal{I}^\sharp}$ is soluble. Therefore, by Theorem 1187, $\mathcal{I}$ is narrowly system truth equational. ■

We establish, next, a connection between narrow system truth equationality and narrow system c-reflectivity by means of a variant of the systemic Suszko operator. This variant of the systemic Suszko operator, denoted $\widehat{\Omega}^{\mathcal{I}^\sharp}$, is not necessarily identical to the systemic Suszko operator $\widehat{\Omega}^{\mathcal{I}}$ itself, unlike the version of the Suszko operator $\widetilde{\Omega}^{\mathcal{I}^\sharp}$, defined in the preceding section, which was introduced only for convenience, but was actually shown to be equivalent to the original version $\widetilde{\Omega}^{\mathcal{I}}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We define the **narrow systemic Suszko operator** $\widetilde{\Omega}^{\mathcal{I}^\sharp}$ by setting, for all $T \in \text{ThSys}(\mathcal{I})$,

$$\widetilde{\Omega}^{\mathcal{I}^\sharp}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}^\sharp(\mathcal{I}) \}.$$

Note that Lemma 1119 and, hence, a hypothetical analog of Corollary 1120, are not applicable in the case of theory systems, since, given $T \in \text{ThSys}(\mathcal{I})$, it may not be the case that $\widetilde{T} \in \text{ThSys}(\mathcal{I})$. On the other hand, as the following lemma shows, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\widetilde{\Omega}^{\mathcal{I}^\sharp}(T) = \widehat{\Omega}^{\mathcal{I}}(T)$. So, for the case of theory systems, all of whose components are nonempty, the two operators do coincide.

Lemma 1189 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $T \in \text{ThSys}^\sharp(\mathcal{I})$,*

$$\widehat{\Omega}^{\mathcal{I}}(T) = \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}^\sharp(\mathcal{I}) \}.$$

Proof: Since $\{T' \in \text{ThSys}^\sharp(\mathcal{I}) : T \leq T'\} \subseteq \{T' \in \text{ThSys}(\mathcal{I}) : T \leq T'\}$, we get

$$\widehat{\Omega}^{\mathcal{I}}(T) \leq \bigcap \{ \Omega(T') : T \leq T' \in \text{ThSys}^\sharp(\mathcal{I}) \}.$$

But, if $T \in \text{ThSys}^\sharp(\mathcal{I})$, then, for all $T' \in \text{ThSys}(\mathcal{I})$, such that $T \leq T'$, we have $T' \in \text{ThSys}^\sharp(\mathcal{I})$. Thus, in this particular case, the two collections above are identical and, therefore, equality holds between the two sides in the displayed formula, which proves the lemma. ■

In analogy with the case of rough system truth equationality, we may introduce the notion of *adequacy* of the narrow system core, which will help in characterizing the relationship between narrow system truth equationality and narrow system c-reflectivity. The following proposition, a “narrow” analog of Proposition 1170, justifies the notion of adequacy that will follow.

Proposition 1190 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \} \leq \widehat{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$,

$$\begin{aligned} \phi \in T_\Sigma & \text{ implies } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) \quad (\text{Definition of } Z^{\mathcal{I}^\sharp}) \\ & \text{ implies } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T). \quad (T \in \text{ThSys}^\sharp(\mathcal{I})) \end{aligned}$$

Hence,

$$\begin{aligned} & \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \} \\ & \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \widehat{\Omega}^{\mathcal{I}}(T) \} \\ & \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } \phi \in T_\Sigma \} \\ & = \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } \vec{\phi} \leq T \} \\ & = \widetilde{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})). \end{aligned}$$

This is the displayed formula in the statement. ■

If the reverse inclusion of that proven in Proposition 1190 holds, then we say that the narrow system core of $\mathcal{I}$ is *adequate*.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow system core $Z^{\mathcal{I}^\sharp}$ of $\mathcal{I}$ is **adequate** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\widehat{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})) \leq \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \}.$$

We can show, in analogy with Corollary 1171, that the solubility of the narrow system core implies its adequacy.

Corollary 1191 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $Z^{\mathcal{I}^\sharp}$ is soluble, then it is adequate.*

Proof: Suppose $Z^{\mathcal{I}^\sharp}$ is soluble and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \mathbf{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \widehat{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})) &= \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } \vec{\phi} \leq T \} \\ &\quad (\text{definition of } \widehat{\Omega}^{\mathcal{I}^\sharp}) \\ &= \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } \phi \in T_\Sigma \} \\ &\quad (T \in \text{ThSys}(\mathcal{I})) \\ &= \bigcap \{ \Omega(T) : T \in \text{ThSys}^\sharp(\mathcal{I}) \text{ and } Z_\Sigma^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T) \}. \\ &\quad (\text{Solubility of } Z^{\mathcal{I}^\sharp}) \end{aligned}$$

Thus, $Z^{\mathcal{I}^\sharp}$ is adequate. ■

In order to prove a partial converse of Corollary 1191, we will employ the following characterization of narrow system c-reflectivity.

Lemma 1192 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly system c-reflective if and only if, for all $T \in \text{ThSys}(\mathcal{I})$ and all $T' \in \text{ThSys}^\sharp(\mathcal{I})$,*

$$\widehat{\Omega}^{\mathcal{I}^\sharp}(T) \leq \Omega(T') \quad \text{implies} \quad T \leq T'.$$

Proof: Suppose, first, that $\mathcal{I}$ is narrowly system c-reflective and let $T \in \text{ThSys}(\mathcal{I})$ and $T' \in \text{ThSys}^\sharp(\mathcal{I})$, such that $\widehat{\Omega}^{\mathcal{I}^\sharp}(T) \leq \Omega(T')$. Then, by definition,

$$\bigcap \{ \Omega(T'') : T \leq T'' \in \text{ThSys}^\sharp(\mathcal{I}) \} \leq \Omega(T').$$

By narrow system c-reflectivity, $\bigcap \{ T'' : T \leq T'' \in \text{ThSys}^\sharp(\mathcal{I}) \} \leq T'$. Thus, $T \leq T'$.

Suppose, conversely, that the displayed condition in the statement holds and let $\mathcal{T} \cup \{T'\} \subseteq \text{ThSys}^\sharp(\mathcal{I})$, such that $\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T')$. Then, since $\mathcal{T} \subseteq \text{ThSys}^\sharp(\mathcal{I})$, we get that

$$\bigcap \{ \Omega(T) : \bigcap \mathcal{T} \leq T'' \in \text{ThSys}^\sharp(\mathcal{I}) \} \leq \Omega(T').$$

By definition, then, $\widehat{\Omega}^{\mathcal{I}^\sharp}(\cap \mathcal{T}) \leq \Omega(T')$, whence, by hypothesis, $\cap \mathcal{T} \leq T'$. This shows that $\mathcal{I}$ is narrowly system c-reflective. ■

We prove, next, a partial converse of Corollary 1191, under the additional assumption that the π -institution $\mathcal{I}$ under consideration is narrowly system c-reflective. This constitutes an analog of Proposition 1172.

Proposition 1193 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a narrowly system c-reflective π -institution based on $\mathbf{F}$. If $Z^{\mathcal{I}^\sharp}$ is adequate, then it is soluble.*

Proof: Suppose $\mathcal{I}$ is narrowly system c-reflective and $Z^{\mathcal{I}^\sharp}$ is adequate. Let $T \in \text{ThSys}^{\mathcal{I}^\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $Z_{\Sigma}^{\mathcal{I}^\sharp}[\phi] \leq \Omega(T)$. By the postulated adequacy of $Z^{\mathcal{I}^\sharp}$, we get that $\widehat{\Omega}^{\mathcal{I}^\sharp}(C(\vec{\phi})) \leq \Omega(T)$. By narrow system truth equationality and Lemma 1192, $C(\vec{\phi}) \leq T$. Therefore, $\phi \in T_{\Sigma}$. We conclude that $Z^{\mathcal{I}^\sharp}$ is soluble. ■

We are now in a position to prove the main characterization theorem relating narrow system truth equationality with narrow system c-reflectivity, an analog of Theorem 1173, which characterized rough system truth equationality in terms of rough system c-reflectivity and the adequacy of the rough system core.

$$\begin{aligned}
 &\text{Narrow System Truth Equationality} \\
 &= Z^{\mathcal{I}^\sharp} \text{ Soluble} \\
 &= Z^{\mathcal{I}^\sharp} \text{ Narrowly Defines Theory Systems} \\
 &= \text{Narrow System c-Reflectivity} \\
 &\quad + Z^{\mathcal{I}^\sharp} \text{ Adequate}
 \end{aligned}$$

Theorem 1194 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly system truth equational if and only if it is narrowly system c-reflective and has an adequate narrow system core.*

Proof: Suppose, first, that $\mathcal{I}$ is narrowly system truth equational. By Theorem 1180, it is narrowly system c-reflective. By Theorem 1185, its narrow system core is soluble. Thus, by Corollary 1191, its narrow system core is also adequate.

Assume, conversely, that $\mathcal{I}$ is narrowly system c-reflective and has an adequate narrow system core. Then, by Proposition 1193, its narrow system core is soluble. Hence, by Theorem 1186, $\mathcal{I}$ is narrowly system truth equational. ■

Based on Proposition 1161 and Theorem 468, it is not difficult to show, in an analog of Corollary 1174, that the characterization theorem, Theorem 889, of system truth equationality in terms of system c-reflectivity and the adequacy of the system core, can be inferred from Theorem 1194.

Corollary 1195 (Theorem 889) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is system truth equational if and only if it is system c-reflective and has an adequate system core.*

Proof: $\mathcal{I}$ is system truth equational if and only if, by Proposition 1161, it is narrowly system truth equational and has theorems, if and only if, by Theorem 1194, it is narrowly system c-reflective, with an adequate narrow system core and has theorems, if and only if, by Theorem 468 and the definitions of system core and narrow system core, it is system c-reflective and has an adequate system core. ■

We now prove an analog of Theorem 1175, which may be perceived either as an alternative characterization of narrow system truth equationality, involving arbitrary $\mathbf{F}$ -algebraic systems, or as a transfer theorem.

Theorem 1196 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is narrowly system truth equational, with witnessing equations τ^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $T \in \mathbf{FiSys}^{\mathcal{I}^\sharp}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,*

$$\phi \in T_\Sigma \quad \text{iff} \quad \tau_\Sigma^A[\phi] \leq \Omega^A(T).$$

Proof: If the postulated condition holds, then it holds, in particular, for the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. This yields immediately that $\mathcal{I}$ is narrowly system truth equational.

Suppose, conversely, that $\mathcal{I}$ is narrowly system truth equational and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T \in \mathbf{FiSys}^{\mathcal{I}^\sharp}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \alpha_\Sigma(\phi) \in T_{F(\Sigma)} & \quad \text{iff} \quad \phi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \Omega(\alpha^{-1}(T)) \\ & \quad \quad \quad (\text{Lemma 6 and hypothesis}) \\ & \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq \alpha^{-1}(\Omega^A(T)) \quad (\text{Proposition 24}) \\ & \quad \text{iff} \quad \tau_{F(\Sigma)}^A[\alpha_\Sigma(\phi)] \leq \Omega^A(T). \quad (\text{Lemma 95}) \end{aligned}$$

Hence, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that the displayed condition holds. ■

We close the section by providing a theorem establishing some inclusion relationships between the various classes introduced in this and the preceding sections.

Theorem 1197 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) If $\mathcal{I}$ is roughly left truth equational, then it is roughly system truth equational;
- (b) If $\mathcal{I}$ is roughly/narrowly truth equational, then it is roughly system truth equational;
- (c) If $\mathcal{I}$ is roughly system truth equational, then it is narrowly system truth equational.
- (d) If $\mathcal{I}$ is narrowly left truth equational, then it is narrowly system truth equational.

Proof:

- (a) Suppose that $\mathcal{I}$ is roughly left truth equational, with witnessing equations τ^b . Then, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. In particular, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Since T is quantified over theory systems, the condition is equivalent to, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Hence, by definition, $\mathcal{I}$ is roughly system truth equational.
- (b) Suppose that $\mathcal{I}$ is roughly/narrowly truth equational with witnessing equations τ^b . By Proposition 1105, this means that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. In particular, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Thus, $\mathcal{I}$ is roughly system truth equational.
- (c) Suppose that $\mathcal{I}$ is roughly system truth equational with witnessing equations τ^b . By definition, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. In particular, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \widetilde{\widetilde{T}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Hence, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in T_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Thus, by Proposition 1177, $\mathcal{I}$ is narrowly system truth equational.
- (d) Suppose that $\mathcal{I}$ is narrowly left truth equational with witnessing equations τ^b . By definition, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{\widetilde{\widetilde{T}}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. In particular, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in \overleftarrow{\widetilde{\widetilde{T}}}_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Hence, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $\phi \in T_\Sigma$ iff $\tau_\Sigma^b[\phi] \leq \Omega(T)$. Thus, by Proposition 1177, $\mathcal{I}$ is narrowly system truth equational.

■

Theorem 1197 establishes the hierarchy of rough/narrow truth equationality properties shown in the diagram.

We need, finally, some examples to show that none of the parts of this hierarchy collapses and, thus, the hierarchy is genuinely as depicted.

We provide, first, an example of a π -institution that is roughly left truth equational, but not roughly/narrowly (family) truth equational.

Example 1198 EXAMPLE NOT FOUND YET!

Next, we provide an example of a π -institution that is roughly left truth equational, but not narrowly left truth equational.

Example 1199 EXAMPLE NOT FOUND YET!

Now, we provide an example of a π -institution which is narrowly left truth equational, but not roughly system truth equational.

Example 1200 EXAMPLE NOT FOUND YET!

Next, we give an example of a π -institution that is roughly/narrowly (family) truth equational, but fails to be roughly left truth equational.

Example 1201 EXAMPLE NOT FOUND YET!

Finally, we give an example of a π -institution that is roughly/narrowly (family) truth equational, but fails to be narrowly left truth equational.

Example 1202 EXAMPLE NOT FOUND YET!

14.7 Availability of Natural Theorems

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall that, by convention, if $\mathcal{I}$ has theorems, then, for every $\Sigma \in |\mathbf{Sign}^b|$, $\mathcal{I}$ has a Σ -theorem, i.e., there exists $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma(\emptyset)$.

On the other hand, recall from Section 2.6 that we say that a π -institution $\mathcal{I}$ has *natural theorems* if there exists a $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)^k$,

$$\vartheta_\Sigma^b(\vec{\phi}) \in C_\Sigma(\emptyset).$$

Furthermore, recall that we denote by $\text{NThm}(\mathcal{I})$ the collection of natural theorems of $\mathcal{I}$.

It is straightforward that having natural theorems is a stronger property than having theorems.

Lemma 1203 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has natural theorems, then it has theorems.*

Proof: Suppose $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b is a natural theorem. Let $\Sigma \in |\mathbf{Sign}^b|$. By convention $\text{SEN}^b(\Sigma) \neq \emptyset$. Let $\vec{\phi} \in \text{SEN}^b(\Sigma)$. Then, we get $\vartheta_\Sigma^b(\vec{\phi}) \in \text{Thm}_\Sigma(\mathcal{I})$. This shows that $\mathcal{I}$ has theorems. ■

On the other hand, it is easy to find examples of π -institutions with theorems that do not possess natural theorems. For example, every π -institution with at least one non-trivial set of sentences $\text{SEN}^b(\Sigma)$, containing both a Σ -theorem and a Σ -non theorem, and with a trivial category of natural transformations, cannot have natural theorems. This follows from the fact that, under these circumstances, no projection natural transformation can be a natural theorem and projection natural transformations are the only ones available because of the triviality of N^b .

Another useful observation is that every π -institution with natural theorems has at least one at-most-unary natural theorem.

Lemma 1204 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has natural theorems, then it has at least one at-most-unary natural theorem.*

Proof: Suppose $\mathcal{I}$ has natural theorems and let $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ be a natural theorem in N^b . If $k = 0$ or 1 , then there is nothing to prove. If $k > 1$, then we define $\vartheta'^b : \text{SEN}^b \rightarrow \text{SEN}^b$ by setting, for all $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$,

$$\vartheta'_\Sigma(\phi) = \vartheta_\Sigma^b(\underbrace{\phi, \phi, \dots, \phi}_k).$$

Since $\vartheta'^b = \vartheta^b \circ \langle p^{1,0}, p^{1,0}, \dots, p^{1,0} \rangle$ and ϑ^b is in N^b , we get that ϑ'^b is in N^b also. Moreover, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\vartheta'_\Sigma(\phi) = \vartheta_\Sigma^b(\phi, \dots, \phi) \in \text{Thm}_\Sigma(\mathcal{I}).$$

Hence ϑ'^b is a unary natural theorem. ■

We have the following characterization of natural theorems involving the local Frege operator.

Theorem 1205 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ a natural transformation in N^b . Then the following conditions are equivalent:*

- (i) $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ is a natural theorem;
- (ii) For every $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \vec{\chi} \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \in \lambda_\Sigma(T);$$

- (iii) For every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \vec{\chi} \in \text{SEN}^b(\Sigma)$,

$$\phi \in \text{Thm}_\Sigma(\mathcal{I}) \quad \text{iff} \quad \langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \in \lambda_\Sigma(\text{Thm}(\mathcal{I})).$$

Proof:

- (i) $\Rightarrow$ (ii) Assume that $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ is a natural theorem. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \vec{\chi} \in \text{SEN}^b(\Sigma)$.

- Suppose $\phi \in T_\Sigma$. Then, since $\vartheta_\Sigma^b(\vec{\chi}) \in \text{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$, we get, by definition of $\lambda(T)$, $\langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \in \lambda_\Sigma(T)$.
- On the other hand, assume $\langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \in \lambda_\Sigma(T)$. Since $\vartheta_\Sigma^b(\vec{\chi}) \in \text{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$, we get, by the definition of $\lambda(T)$, $\phi \in T_\Sigma$.

- (ii) $\Rightarrow$ (iii) Trivial.

- (iii) $\Rightarrow$ (i) Suppose that (iii) holds. Let $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$ and $\vec{\chi} \in \text{SEN}^b(\Sigma)$.

- If $\phi \in \text{Thm}_\Sigma(\mathcal{I})$, then, by hypothesis, $\langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \in \lambda_\Sigma(\text{Thm}(\mathcal{I}))$, whence, $\vartheta_\Sigma^b(\vec{\chi}) \in \text{Thm}_\Sigma(\mathcal{I})$.
- If $\phi \notin \text{Thm}_\Sigma(\mathcal{I})$, then, by hypothesis, $\langle \phi, \vartheta_\Sigma^b(\vec{\chi}) \rangle \notin \lambda_\Sigma(\text{Thm}(\mathcal{I}))$. Thus, $\vartheta_\Sigma^b(\vec{\chi}) \notin \text{Thm}_\Sigma(\mathcal{I})$.

We conclude that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\chi} \in \text{SEN}^b(\Sigma)$, $\vartheta_\Sigma^b(\vec{\chi}) \in \text{Thm}_\Sigma(\mathcal{I})$. Therefore, ϑ^b is a natural theorem.

■

We provide two additional equivalent conditions in the theorem following the next lemma.

Lemma 1206 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and $\vartheta^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ a natural transformation in N^b . If ϑ^b is a natural theorem, then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $\Sigma \in |\mathbf{Sign}|$ and all $\tilde{\chi} \in \mathbf{SEN}(\Sigma)$, $\vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \in C_{\Sigma}^{\mathcal{I}, \mathcal{A}}(\emptyset)$, i.e., $\vartheta^{\mathcal{A}}$ is a natural theorem of $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.*

Proof: Since ϑ^b is a natural theorem, for all $\Sigma \in |\mathbf{Sign}|$ and all $\tilde{\chi} \in \mathbf{SEN}^b(\Sigma)$,

$$\vartheta_{F(\Sigma)}^{\mathcal{A}}(\alpha_{\Sigma}(\tilde{\chi})) = \alpha_{\Sigma}(\vartheta_{\Sigma}^b(\tilde{\chi})) \in \alpha_{\Sigma}(\text{Thm}_{\Sigma}(\mathcal{I})) \subseteq C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\emptyset).$$

By the surjectivity of $\langle F, \alpha \rangle$ the conclusion follows. ■

Theorem 1207 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and $\vartheta^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ a natural transformation in N^b . Then the following conditions are equivalent:*

- (i) $\vartheta^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ is a natural theorem;
- (ii) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad (\forall \tilde{\chi} \in \mathbf{SEN}(\Sigma))(\langle \phi, \vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \rangle \in \tilde{\lambda}_{\Sigma}^{\mathcal{I}, \mathcal{A}}(T));$$

- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,

$$\phi \in C_{\Sigma}^{\mathcal{I}, \mathcal{A}}(\emptyset) \quad \text{iff} \quad (\forall \tilde{\chi} \in \mathbf{SEN}(\Sigma))(\langle \phi, \vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \rangle \in \tilde{\lambda}_{\Sigma}^{\mathcal{I}, \mathcal{A}}(C^{\mathcal{I}, \mathcal{A}}(\emptyset))).$$

Proof:

- (i) $\Rightarrow$ (ii) Assume that $\vartheta^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ is a natural theorem and let $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathbf{SEN}(\Sigma)$. By Lemma 1206, for all $\tilde{\chi} \in \mathbf{SEN}(\Sigma)$, $\vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \in C_{\Sigma}^{\mathcal{I}, \mathcal{A}}(\emptyset)$.

- If $\phi \in T_{\Sigma}$, then, clearly, for all $\tilde{\chi} \in \mathbf{SEN}(\Sigma)$, and all $T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\phi \in T'_{\Sigma}$ and $\vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \in T'_{\Sigma}$. Hence, $\langle \phi, \vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \rangle \in \tilde{\lambda}_{\Sigma}^{\mathcal{I}, \mathcal{A}}(T)$.
- If, for all $\tilde{\chi} \in \mathbf{SEN}(\Sigma)$, $\langle \phi, \vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \rangle \in \tilde{\lambda}_{\Sigma}^{\mathcal{I}, \mathcal{A}}(T)$, then, in particular, for all $\tilde{\chi} \in \mathbf{SEN}(\Sigma)$, $\langle \phi, \vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \rangle \in \lambda_{\Sigma}^{\mathcal{A}}(T)$. Since $\vartheta_{\Sigma}^{\mathcal{A}}(\tilde{\chi}) \in T_{\Sigma}$, we conclude that $\phi \in T_{\Sigma}$.

(ii) $\Rightarrow$ (iii) Trivial.

(iii) $\Rightarrow$ (iv) Suppose that (iii) holds. Consider, first, the trivial algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with the single signature object $*$ and such that $\text{SEN}(\ast) = \{0\}$. Then, we have $\langle 0, \vartheta_{\Sigma}^{\mathcal{A}}(\vec{0}) \rangle = \langle 0, 0 \rangle \in \{\langle 0, 0 \rangle\} = \widetilde{\lambda}_{\ast}^{\mathcal{I}, \mathcal{A}}(\emptyset)$. If $\emptyset \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, then this would imply, by hypothesis, that $0 \in \emptyset$, a contradiction. Thus, $\emptyset \notin \text{ThFam}^{\mathcal{I}}(\mathcal{A})$. This shows that $\mathcal{I}$ has theorems.

Let, now, $\Sigma \in |\mathbf{Sign}^b|$ and $\vec{\chi} \in \text{SEN}(\Sigma)$. Take a theorem $t \in \text{Thm}_{\Sigma}(\mathcal{I})$. Then, by hypothesis, $\langle t, \vartheta_{\Sigma}^b(\vec{\chi}) \rangle \in \widetilde{\lambda}_{\Sigma}^{\mathcal{I}}(\text{Thm}(\mathcal{I})) \subseteq \lambda_{\Sigma}(\text{Thm}(\mathcal{I}))$. Thus, since $t \in \text{Thm}_{\Sigma}(\mathcal{I})$, we must have $\vartheta_{\Sigma}^b(\vec{\chi}) \in \text{Thm}_{\Sigma}(\mathcal{I})$. But $\Sigma \in |\mathbf{Sign}^b|$ and $\vec{\chi} \in \text{SEN}^b(\Sigma)$ were arbitrary, whence, we conclude that ϑ^b is a natural theorem. ■

We saw that availability of natural theorems is a strictly stronger condition than availability of theorems. We have the following theorem, which follows from preceding results.

Theorem 1208 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

(a) *If $\mathcal{I}$ has natural theorems, then there exists $\tau : (\text{SEN}^b)^k \rightarrow (\text{SEN}^b)^2$ in N^b , such that, for all $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,*

$$\phi \in T_{\Sigma} \quad \text{iff}, \quad (\forall \vec{\chi} \in \text{SEN}(\Sigma)) (\tau_{\Sigma}^{\mathcal{A}}(\phi, \vec{\chi}) \subseteq \widetilde{\lambda}_{\Sigma}^{\mathcal{I}, \mathcal{A}}(T));$$

(b) *If the condition in the conclusion of (a) holds, then $\mathcal{I}$ has theorems.*

Proof:

(a) Suppose $\mathcal{I}$ has natural theorems and let $\vartheta^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ be a natural theorem. Then, we define $\tau^b : (\text{SEN}^b)^{k+1} \rightarrow (\text{SEN}^b)^2$, by setting

$$\tau^b := \{ \langle p^{k+1,0}, \vartheta^b \circ \langle p^{k+1,1}, \dots, p^{k+1,k} \rangle \rangle \}.$$

Then the conclusion follows from Theorem 1207.

(b) Suppose that the conclusion of Part (a) holds. Consider the trivial algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with the single signature object $*$ and such that $\text{SEN}(\ast) = \{0\}$. If $\mathcal{I}$ does not have theorems, then $\emptyset \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $0 \notin \emptyset$, we must have, by hypothesis, $\langle 0, 0 \rangle = \langle 0, \vartheta_{\Sigma}^{\mathcal{A}}(\vec{0}) \rangle \notin \widetilde{\lambda}_{\ast}^{\mathcal{I}, \mathcal{A}}(\emptyset) = \{\langle 0, 0 \rangle\}$, a contradiction. Therefore, $\mathcal{I}$ has theorems.

■

We may think of a π -institution that has theorems, but not natural theorems, as having a syntactic deficiency, i.e., not having enough natural transformations in its category of natural transformations to express theoremhood. So in an analogous way with the one used to formulate similar properties through the Leibniz property of the reflexive core and the adequacy of the Suszko core, we make the following definition, taking cue from Theorem 1205.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **Lindenbaum core** $F^{\mathcal{I}}$ of $\mathcal{I}$ is defined by

$$F^{\mathcal{I}} = \{ \sigma^b \in N^b : (\forall T \in \text{ThFam}(\mathcal{I})) (\forall \Sigma \in |\mathbf{Sign}^b|) (\forall \vec{\chi} \in \mathbf{SEN}^b(\Sigma)) \\ (\{ \langle \phi, \sigma_{\Sigma}^b(\vec{\chi}) \rangle : \phi \in T_{\Sigma} \} \subseteq \widetilde{\lambda}_{\Sigma}^{\mathcal{I}}(T)) \}.$$

It is not difficult to show that, in case $\mathcal{I}$ has theorems, then the Lindenbaum core consists exactly of the natural theorems of $\mathcal{I}$, $F^{\mathcal{I}} = \text{NThm}(\mathcal{I})$.

Proposition 1209 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has theorems, then $F^{\mathcal{I}} = \text{NThm}(\mathcal{I})$.*

Proof: Suppose that $\mathcal{I}$ has theorems.

Assume $\sigma^b \in F^{\mathcal{I}}$ and let $\Sigma \in |\mathbf{Sign}^b|$, $\vec{\chi} \in \mathbf{SEN}^b(\Sigma)$. Since $\mathcal{I}$ has theorems, there exists $t \in \text{Thm}_{\Sigma}(\mathcal{I})$. Then, by hypothesis and the definition of $F^{\mathcal{I}}$,

$$\langle t, \sigma_{\Sigma}^b(\vec{\chi}) \rangle \in \widetilde{\lambda}_{\Sigma}^{\mathcal{I}}(\text{Thm}(\mathcal{I})) \subseteq \lambda_{\Sigma}(\text{Thm}(\mathcal{I})).$$

Thus, since $t \in \text{Thm}_{\Sigma}(\mathcal{I})$, $\sigma_{\Sigma}^b(\vec{\chi}) \in \text{Thm}_{\Sigma}(\mathcal{I})$. Since $\Sigma \in |\mathbf{Sign}^b|$ and $\vec{\chi} \in \mathbf{SEN}^b(\Sigma)$ were arbitrary, $\sigma^b \in \text{NThm}(\mathcal{I})$. Therefore, we get that $F^{\mathcal{I}} \subseteq \text{NThm}(\mathcal{I})$.

Suppose, conversely, that $\sigma^b \in \text{NThm}(\mathcal{I})$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \vec{\chi} \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_{\Sigma}$ and $T \leq T' \in \text{ThFam}(\mathcal{I})$. Then, we get $\phi \in T'_{\Sigma}$ and $\sigma_{\Sigma}^b(\vec{\chi}) \in T'_{\Sigma}$, whence

$$\phi \in T'_{\Sigma} \quad \text{iff} \quad \sigma_{\Sigma}^b(\vec{\chi}) \in T'_{\Sigma}.$$

That is, for all $T \leq T' \in \text{ThFam}(\mathcal{I})$, $\langle \phi, \sigma_{\Sigma}^b(\vec{\chi}) \rangle \in \lambda_{\Sigma}(T')$. Hence, $\langle \phi, \sigma_{\Sigma}^b(\vec{\chi}) \rangle \in \widetilde{\lambda}_{\Sigma}^{\mathcal{I}}(T)$. This shows that $\sigma^b \in F^{\mathcal{I}}$, whence $\text{NThm}(\mathcal{I}) \subseteq F^{\mathcal{I}}$. ■

In the remainder of the section, we show that a property analogous to adequacy, coupled with possession of theorems, guarantees the existence of natural theorems. The following lemma partly justifies the definition of adequacy.

Proposition 1210 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,*

$$\bigcap \{ \lambda(T) : \{ \langle \phi, F_{\Sigma}^{\mathcal{I}}(\vec{\chi}) \rangle : \vec{\chi} \in \mathbf{SEN}^b(\Sigma) \} \subseteq \lambda_{\Sigma}(T) \} \leq \widetilde{\lambda}^{\mathcal{I}}(C(\phi)).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. By the definition of the Lindenbaum core, for all $T \in \text{ThFam}(\mathcal{I})$ and for all $\tilde{\chi} \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{implies} \quad \langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle \subseteq \tilde{\lambda}_\Sigma^\mathcal{I}(T) \subseteq \lambda_\Sigma(T).$$

Therefore, we get

$$\begin{aligned} & \{T \in \text{ThFam}(\mathcal{I}) : \phi \in T_\Sigma\} \\ & \subseteq \{T \in \text{ThFam}(\mathcal{I}) : \{\langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle : \tilde{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_\Sigma(T)\}. \end{aligned}$$

This, now, yields

$$\bigcap \{\lambda(T) : \{\langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle : \tilde{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_\Sigma(T)\} \leq \tilde{\lambda}^\mathcal{I}(C(\phi)),$$

i.e., the displayed formula in the statement. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the Lindenbaum core $F^\mathcal{I}$ is **adequate** if the reverse inclusion of the one proved in Proposition 1210 holds, i.e., if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\tilde{\lambda}(C(\phi)) \leq \bigcap \{\lambda(T) : \{\langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle : \tilde{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_\Sigma(T)\}.$$

Theorem 1211 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ has natural theorems if and only if it has theorems and its Lindenbaum core is adequate.*

Proof: If $\mathcal{I}$ has natural theorems, then, by Lemma 1203, it has theorems. Moreover, by Proposition 1209, $F^\mathcal{I} = \text{NThm}(\mathcal{I})$. Now consider $\tau^b \in \text{NThm}(\mathcal{I})$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, such that, for all $\tilde{\chi} \in \text{SEN}^b(\Sigma)$, $\langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle \subseteq \lambda_\Sigma(T)$. Since $F^\mathcal{I} = \text{NThm}(\mathcal{I})$, we get $F_\Sigma^\mathcal{I}(\tilde{\chi}) \subseteq \text{Thm}_\Sigma(\mathcal{I}) \subseteq T_\Sigma$. Thus, $\phi \in T_\Sigma$. This shows that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} & \{T \in \text{ThFam}(\mathcal{I}) : (\{\langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle : \tilde{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_\Sigma(T))\} \\ & \subseteq \{T \in \text{ThFam}(\mathcal{I}) : \phi \in T_\Sigma\}. \end{aligned}$$

Hence, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$\tilde{\lambda}(C(\phi)) \leq \bigcap \{\lambda(T) : \{\langle \phi, F_\Sigma^\mathcal{I}(\tilde{\chi}) \rangle : \tilde{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_\Sigma(T)\}.$$

This proves that $F^\mathcal{I}$ is adequate.

Assume, conversely, that $\mathcal{I}$ has theorems and $F^\mathcal{I}$ is adequate.

Note that, if $\text{Thm}(\mathcal{I}) = \text{SEN}^b$, then $p^{1,0} : \text{SEN}^b \rightarrow \text{SEN}^b$ is a natural theorem. So we may assume that $\overline{\theta} \not\subseteq \text{Thm}(\mathcal{I}) \not\subseteq \text{SEN}^b$. Let $\Sigma \in |\mathbf{Sign}^b|$, $t \in \text{Thm}_\Sigma(\mathcal{I})$ and $\phi \in \text{SEN}^b(\Sigma) \setminus \text{Thm}_\Sigma(\mathcal{I})$. Then, we get

$$\langle \phi, t \rangle \in \lambda_\Sigma(C(\phi)) \quad \text{but} \quad \langle \phi, t \rangle \notin \lambda_\Sigma(\text{Thm}(\mathcal{I})).$$

Thus, if $F^{\mathcal{I}} = \emptyset$, then

$$\text{Thm}(\mathcal{I}) \in \{T \in \text{ThFam}(\mathcal{I}) : \{\langle \phi, F_{\Sigma}^{\mathcal{I}}(\vec{\chi}) \rangle : \vec{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_{\Sigma}(T)\}.$$

So $\langle \phi, t \rangle \notin \bigcap \{\lambda_{\Sigma}(T) : \{\langle \phi, F_{\Sigma}^{\mathcal{I}}(\vec{\chi}) \rangle : \vec{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_{\Sigma}(T)\}$. Since $\langle \phi, t \rangle \in \bigcap \{\lambda_{\Sigma}(T) : \phi \in T_{\Sigma}\}$, we get that

$$\tilde{\lambda}(C(\phi)) \not\subseteq \bigcap \{\lambda(T) : \{\langle \phi, F_{\Sigma}^{\mathcal{I}}(\vec{\chi}) \rangle : \vec{\chi} \in \text{SEN}^b(\Sigma)\} \subseteq \lambda_{\Sigma}(T)\},$$

contrary to the postulated adequacy of $F^{\mathcal{I}}$. Thus, since $\mathcal{I}$ has theorems, we get, by Proposition 1209, $\text{NThm}(\mathcal{I}) = F^{\mathcal{I}} \neq \emptyset$, that is, $\mathcal{I}$ has natural theorems as well. ■

We close the section by showing that having natural theorems is a property that transfers from a π -institution to all $\mathcal{I}$ -gmatrix families of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.

Theorem 1212 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ has natural theorems if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, the $\mathcal{I}$ -gmatrix $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ has natural theorems.*

Proof: The “if” is clear by considering the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and taking into account the fact that $C^{\mathcal{I}, \mathcal{F}} = C$. The “only if” was proven in Lemma 1206. ■

Chapter 15

The Syntactic Leibniz Hierarchy: Basement II

15.1 Introduction

This chapter deals with the syntactic rough/narrow monotonicity hierarchy, which forms the syntactic analog of the rough/narrow monotonicity hierarchy, studied in Chapter 7. We look at the classes of syntactically roughly/narrowly family monotone, syntactically roughly/narrowly system monotone and syntactically narrowly right monotone π -institutions.

In Section 15.2, we study *syntactic narrow family monotonicity*, the syntactic analog of rough/narrow family monotonicity. To introduce this class, one needs, first, to either be able to apply the constituent properties of natural transformations modulo rough representatives of theory families or relativize them to the collection $\text{ThFam}^{\sharp}(\mathcal{I})$ of theory families without empty components. Let us take, for instance, reflexivity. Consider a collection I^b of natural transformations in N^b , with two distinguished arguments. We say that I^b is *roughly family reflexive* if, for every theory family T , all signatures Σ and all Σ -sentences ϕ ,

$$I_{\Sigma}^b[\phi, \phi] \leq \tilde{T}.$$

We say that I^b is *narrowly family reflexive* if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ ,

$$I_{\Sigma}^b[\phi, \phi] \leq T.$$

It is shown that these two properties are identical. Similar results are proven for rough/narrow family symmetry, rough/narrow family transitivity, rough/narrow family compatibility and rough/narrow family modus ponens, which are all defined analogously. We say that a π -institution $\mathcal{I}$ is *syntactically roughly/narrowly family monotone* if there exists a collection I^b of natural transformations in N^b , with two distinguished arguments, such that I^b satisfies narrow family reflexivity, narrow family transitivity, narrow family compatibility and narrow family modus ponens. If $\mathcal{I}$ is syntactically narrow family monotone, with witnessing transformations I^b , then, for every $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overset{\leftarrow}{I}^b(T)$ is a congruence system on $\mathbf{F}$ compatible with T .

This allows showing that $\overset{\leftarrow}{I}^b(T) = \Omega(T)$, that is, I^b narrowly defines Leibniz congruence systems of theory families in $\mathcal{I}$. It follows that syntactic narrow family monotonicity implies (semantic) narrow family monotonicity.

To provide an intrinsic characterization of syntactic narrow family monotonicity, we introduce the *rough/narrow reflexive core* of $\mathcal{I}$. It may be defined in two apparently different ways, one from the rough and one from the narrow point of view, which, however, turn out to be equivalent. The *rough reflexive core* $\tilde{R}^{\mathcal{I}}$ consists of all those natural transformations ρ^b in N^b , with two distinguished arguments, such that, for all $T \in \text{ThFam}(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ , $\rho_{\Sigma}^b[\phi, \phi] \leq \tilde{T}$. The *narrow reflexive core* $R^{\mathcal{I}^{\sharp}}$ is

defined similarly, but quantifying T over $\text{ThFam}^{\sharp}(\mathcal{I})$ and replacing the inequality by $\rho_{\Sigma}^b[\phi, \psi] \leq T$. We have that $\tilde{R}^{\mathcal{I}} = R^{\mathcal{I}^{\sharp}}$. We show that, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a reflexive, symmetric relation system on $\mathbf{F}$ that has the compatibility property. Thus, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ only falls short of becoming a congruence system compatible with T because of $R^{\mathcal{I}^{\sharp}}$ possibly lacking the narrow family transitivity and the narrow family modus ponens properties. If $\mathcal{I}$ happens to be syntactically narrow family monotone, then $R^{\mathcal{I}^{\sharp}}$ has the narrow family modus ponens and, as a consequence, it is also narrow family transitive. Conversely, if $R^{\mathcal{I}^{\sharp}}$ has the narrow family modus ponens, then the π -institution $\mathcal{I}$ is syntactically family narrow monotone, with witnessing transformations $R^{\mathcal{I}^{\sharp}}$. That is, the narrow family modus ponens property of $R^{\mathcal{I}^{\sharp}}$ intrinsically characterizes syntactic narrow family monotonicity. Additionally, $\mathcal{I}$ is syntactically narrowly family monotone if and only if $R^{\mathcal{I}^{\sharp}}$ narrowly defines Leibniz congruence systems of theory families, in the sense that, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T) = \Omega(T)$.

The second part of Section 15.2 deals with devising a characterization of syntactic narrow family monotone π -institutions as a subclass of narrow family monotone π -institutions. Recalling the case of syntactic protoalgebraicity versus protoalgebraicity, where the separation was attained by the Leibniz property of the reflexive core $R^{\mathcal{I}}$ of the π -institution $\mathcal{I}$, we must devise here an analogous property for the narrow reflexive core $R^{\mathcal{I}^{\sharp}}$. Due to the fact that we are dealing with theory families with nonempty components, this analog involves additional complications. First, we define, for every signature Σ and all Σ -sentences ϕ, ψ , the collection $[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$ of all theory families $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, which contain $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]$. We then set $\min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$ for the family of all minimal elements in $[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$. Note that, if $C(R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]) \in \text{ThFam}^{\sharp}(\mathcal{I})$, then $\min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]] = \{C(R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi])\}$. Thus, this construct is meant to handle the difficulty encountered in the special case in which $C(R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi])$ happens to have some empty components. We say that the narrow reflexive core $R^{\mathcal{I}^{\sharp}}$ is *Leibniz* if, for all signatures Σ , all Σ -sentences ϕ, ψ and all $T \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$. It turns out that if $R^{\mathcal{I}^{\sharp}}$ has the narrow family modus ponens, then it is Leibniz. Ideally, to have the prototypical example of syntactic protoalgebraicity versus protoalgebraicity applicable without changes, we would like to have that, under narrow family monotonicity, $R^{\mathcal{I}^{\sharp}}$ being Leibniz implies that it has the narrow family modus ponens. This presents some obstacles and we are only able to advance under an additional hypothesis on the π -institution $\mathcal{I}$, thus obtaining only a partial result. Given a signature Σ and Σ -sentences ϕ, ψ , $\mathcal{I}$ is called $\langle \Sigma, \phi, \psi \rangle$ -*reflexively covered* if, for all $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, there exists $T' \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, such that $T' \leq T$. Moreover, we say that $\mathcal{I}$ is *reflexively covered* if, for all signatures Σ and all Σ -sentences ϕ, ψ , $\mathcal{I}$ is $\langle \Sigma, \phi, \psi \rangle$ -reflexively covered. We do show that, if $\mathcal{I}$ is reflexively covered,

and narrowly family monotone, then $R^{\mathcal{I}^\sharp}$ being Leibniz implies that $R^{\mathcal{I}^\sharp}$ has the narrow family modus ponens. This enables us to show that, for reflexively covered π -institutions $\mathcal{I}$, $\mathcal{I}$ is syntactically narrowly family monotone if and only if it is narrowly family monotone and has a Leibniz narrow reflexive core.

In Section 15.3, we study *syntactic narrow system monotonicity*, a syntactic analog of narrow system monotonicity. We start by relativizing system reflexivity, system symmetry, system transitivity, system compatibility and system modus ponens of a collection I^b of natural transformations to the collection $\text{ThSys}^\sharp(\mathcal{I})$ of theory systems without empty components, thus obtaining the corresponding narrow versions of these properties. A π -institution $\mathcal{I}$ is called *syntactically narrowly system monotone* if there exists a collection I^b of natural transformations in N^b , with two distinguished arguments, which is narrowly system reflexive, narrowly system transitive, has the narrow system compatibility and satisfies the narrow system modus ponens. If $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations I^b , then, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\overleftarrow{I^b}(T) = \Omega(T)$, that is, I^b narrowly defines Leibniz congruence systems of theory systems in $\mathcal{I}$. This yields that syntactic narrow system monotonicity implies narrow system monotonicity, its semantic counterpart.

The introduction of the *narrow system reflexive core* serves, among other things, to intrinsically characterize syntactic narrow system monotonicity. The *narrow system reflexive core* $R^{\mathcal{I}^s}$ of $\mathcal{I}$ consists of all natural transformations ρ^b in N^b , with two distinguished arguments, such that, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ ,

$$\rho_\Sigma^b[\phi, \phi] \leq T.$$

It turns out that, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\overleftarrow{R^{\mathcal{I}^s}}(T)$ is a reflexive and symmetric relation system on $\mathbf{F}$ and satisfies the compatibility property. Moreover, if $\mathcal{I}$ happens to be syntactically narrowly system monotone, then $R^{\mathcal{I}^s}$ also satisfies the narrow system modus ponens and, as a result, it is narrowly system transitive as well. Conversely, if $R^{\mathcal{I}^s}$ has the narrow system modus ponens, then $\mathcal{I}$ is syntactically narrowly system monotone with witnessing transformations $R^{\mathcal{I}^s}$. Thus, $R^{\mathcal{I}^s}$ having the narrow system modus ponens intrinsically characterizes syntactic narrow system monotonicity.

In the second part of Section 15.3, we use a Leibniz like property of the narrow system reflexive core in order to provide a partial characterization of syntactically narrowly system monotone π -institutions inside the class of narrowly system monotone π -institutions. Since the steps are similar to those employed in Section 15.2, which were described in some detail above, we only give a rough outline. We again define, for every signature Σ and all Σ -sentences ϕ, ψ , the collection

$$[R_\Sigma^{\mathcal{I}^s}[\phi, \psi]] = \{T \in \text{ThSys}^\sharp(\mathcal{I}) : R_\Sigma^{\mathcal{I}^s}[\phi, \psi] \leq T\}.$$

We then set $\min[R_{\Sigma}^{\mathcal{I}s}[\phi, \psi]]$ to be the subcollection of its minimal elements. We say that the narrow system reflexive core $R^{\mathcal{I}s}$ is *Leibniz* if, for all signatures Σ , all Σ -sentences ϕ, ψ and all $T \in \min[R_{\Sigma}^{\mathcal{I}s}[\phi, \psi]]$, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$. We show that, if $R^{\mathcal{I}s}$ has the narrow system modus ponens, then it is Leibniz. Ideally, we would have liked to be able to show that, provided that $\mathcal{I}$ is narrowly system monotone, the converse implication also holds. However, we are able to show this only for a certain subclass of π -institutions. For a fixed signature Σ and fixed Σ -sentences ϕ, ψ , we say that $\mathcal{I}$ is $\langle \Sigma, \phi, \psi \rangle$ -system reflexively covered if, for all $T \in [R_{\Sigma}^{\mathcal{I}s}[\phi, \psi]]$, there exists $T' \in \min[R_{\Sigma}^{\mathcal{I}s}[\phi, \psi]]$, such that $T' \leq T$. $\mathcal{I}$ is called *system reflexively covered* if it is $\langle \Sigma, \phi, \psi \rangle$ -system reflexively covered, for all signatures Σ and all Σ -sentences ϕ, ψ . We do show that, for system reflexively covered π -institutions $\mathcal{I}$, if $\mathcal{I}$ is narrowly system monotone and $R^{\mathcal{I}s}$ is Leibniz, then $R^{\mathcal{I}s}$ has the narrow system modus ponens in $\mathcal{I}$. As a consequence, we get that, for system reflexively covered π -institutions $\mathcal{I}$, $\mathcal{I}$ is syntactically narrowly system monotone if and only if it is narrowly system monotone and has a Leibniz narrow system reflexive core.

In Section 15.4, we turn to a third type of syntactic narrow monotonicity. We say that a π -institution $\mathcal{I}$ is *syntactically narrowly right monotone* if there exists a collection I^b of natural transformations in N^b , with two distinguished arguments, that satisfies narrow right reflexivity, narrow right transitivity, narrow right compatibility and narrow right modus ponens. The meaning of “right” in these terms is that, in any of them, the theory family T , universally quantified over $\text{ThFam}^{\sharp}(\mathcal{I})$, is replaced in the relevant condition by $\overleftarrow{T}$. E.g., I^b is *narrowly right transitive* if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ, ψ, χ , $I_{\Sigma}^b[\phi, \psi] \leq \overleftarrow{T}$ and $I_{\Sigma}^b[\psi, \chi] \leq \overleftarrow{T}$ imply $I_{\Sigma}^b[\phi, \chi] \leq \overleftarrow{T}$. *Narrow right reflexivity*, *narrow right symmetry* and *narrow right compatibility* are defined similarly. On the other hand, *narrow right modus ponens* is defined by stipulating that, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ, ψ , $\phi \in \overleftarrow{T}_{\Sigma}$ and $I_{\Sigma}^b[\phi, \psi] \leq \overleftarrow{T}$ imply $\psi \in \overleftarrow{T}_{\Sigma}$. It turns out that all properties above, besides narrow right modus ponens, are equivalent to their narrow family counterparts. Hence, the only feature that differentiates syntactic narrow right monotonicity from syntactic narrow family monotonicity is the use of narrow right modus ponens instead of narrow family modus ponens.

If $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations I^b , then I^b narrowly defines Leibniz congruence systems of theory families up to arrow, in the sense that, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{I^b}(T) = \Omega(\overleftarrow{T})$. This yields that syntactic narrow right monotonicity implies (semantic) narrow right monotonicity, its semantic counterpart. Next, we reuse the narrow reflexive core $R^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$, introduced in Section 15.2, to intrinsically characterize syntactic narrow right monotonicity. We show that, if $\mathcal{I}$ is syntacti-

cally narrowly right monotone, then $R^{\mathcal{I}^\sharp}$ has the narrow right modus ponens. Moreover, if $R^{\mathcal{I}^\sharp}$ has the narrow right modus ponens, then it is narrowly right transitive. This allows showing that, if $R^{\mathcal{I}^\sharp}$ has the narrow right modus ponens, then $\mathcal{I}$ is syntactically narrowly right monotone. Thus, $R^{\mathcal{I}^\sharp}$ having the narrow right modus ponens characterizes syntactic narrow right monotonicity. The section ends with a characterization, also using the narrow reflexive core, of those narrowly right monotone π -institutions that are syntactically narrowly right monotone. Here the deciding condition is that the narrow reflexive core be *right Leibniz*. We omit the details of this characterization, since they parallel those described previously for both syntactic narrow family and syntactic narrow system monotonicity.

15.2 Syntactic Narrow Family Monotonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 7 that $\mathcal{I}$ is *roughly/narrowly family monotone* if, for all $T, T' \in \text{ThFam}^\sharp(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

In this section we introduce and study a syntactic analog of this concept.

First, we relativize family reflexivity, family symmetry, family transitivity, family compatibility and family modus ponens to $\text{ThFam}^\sharp(\mathcal{I})$.

Let, as above, $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Moreover, suppose that $I^b \subseteq N^b$ is a collection of natural transformations in N^b , with two distinguished arguments.

- I^b is **roughly family reflexive** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$I_\Sigma^b[\phi, \phi] \leq \tilde{T};$$

- I^b is **narrowly family reflexive** if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$I_\Sigma^b[\phi, \phi] \leq T.$$

As the following lemma establishes rough and narrow family reflexivity are identical properties.

Lemma 1213 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a family of natural transformations in N^b , with two distinguished arguments. I^b is roughly family reflexive if and only if it is narrowly family reflexive.*

Proof: Suppose, first, that I^b is roughly family reflexive and consider $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Since $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, we have $\tilde{T} = T$, whence, by rough family reflexivity, $I_{\Sigma}^b[\phi, \phi] \leq \tilde{T} = T$. Thus, I^b is narrowly family reflexive.

Suppose, conversely, that I^b is narrowly family reflexive and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. Since $\tilde{T} \in \text{ThFam}^{\sharp}(\mathcal{I})$, we get, by narrow family reflexivity, $I_{\Sigma}^b[\phi, \phi] \leq \tilde{T}$. Thus, I^b is roughly family reflexive. ■

Let, again, $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a collection of natural transformations in N^b , with two distinguished arguments.

- I^b is **roughly family symmetric** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \leq \tilde{T} \quad \text{implies} \quad I_{\Sigma}^b[\psi, \phi] \leq \tilde{T};$$

- I^b is **narrowly family symmetric** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \leq T \quad \text{implies} \quad I_{\Sigma}^b[\psi, \phi] \leq T.$$

Similarly to rough and narrow family reflexivity, rough and narrow family symmetry coincide.

Lemma 1214 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a family of natural transformations in N^b , with two distinguished arguments. I^b is roughly family symmetric if and only if it is narrowly family symmetric.*

Proof: Suppose, first, that I^b is roughly family symmetric and consider $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $I_{\Sigma}^b[\phi, \psi] \leq T$. Since $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, we have $\tilde{T} = T$, whence, by hypothesis, $I_{\Sigma}^b[\phi, \psi] \leq \tilde{T}$. Applying rough family symmetry, we get $I_{\Sigma}^b[\psi, \phi] \leq \tilde{T} = T$. Thus, I^b is narrowly family symmetric.

Suppose, conversely, that I^b is narrowly family symmetric and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $I_{\Sigma}^b[\phi, \psi] \leq \tilde{T}$. Since $\tilde{T} \in \text{ThFam}^{\sharp}(\mathcal{I})$, we get, by narrow family symmetry, $I_{\Sigma}^b[\psi, \phi] \leq \tilde{T}$. Thus, I^b is roughly family symmetric. ■

Let, once more, $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a collection of natural transformations in N^b , with two distinguished arguments.

- I^b is **roughly family transitive** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$,

$$I_\Sigma^b[\phi, \psi] \cup I_\Sigma^b[\psi, \chi] \leq \tilde{T} \quad \text{implies} \quad I_\Sigma^b[\phi, \chi] \leq \tilde{T};$$

- I^b is **narrowly family transitive** if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$,

$$I_\Sigma^b[\phi, \psi] \cup I_\Sigma^b[\psi, \chi] \leq T \quad \text{implies} \quad I_\Sigma^b[\phi, \chi] \leq T.$$

Rough and narrow family transitivity also coincide.

Lemma 1215 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a family of natural transformations in N^b , with two distinguished arguments. I^b is roughly family transitive if and only if it is narrowly family transitive.*

Proof: Similar to the proof of Lemma 1214. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a collection of natural transformations in N^b , with two distinguished arguments.

- I^b is **roughly family compatible** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\sigma^b \in N^b$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$,

$$\bigcup_{i < k} \overset{\leftrightarrow}{I}_\Sigma^b[\phi_i, \psi_i] \leq \tilde{T} \quad \text{implies} \quad I_\Sigma^b[\sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi})] \leq \tilde{T};$$

- I^b is **narrowly family compatible** if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all $\sigma^b \in N^b$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$,

$$\bigcup_{i < k} \overset{\leftrightarrow}{I}_\Sigma^b[\phi_i, \psi_i] \leq T \quad \text{implies} \quad I_\Sigma^b[\sigma_\Sigma^b(\vec{\phi}), \sigma_\Sigma^b(\vec{\psi})] \leq T.$$

Rough and narrow family transitivity also coincide.

Lemma 1216 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a family of natural transformations in N^b , with two distinguished arguments. I^b is roughly family compatible if and only if it is narrowly family compatible.*

Proof: Similar to the proof of Lemma 1214. ■

Finally, we define the property of possessing the rough and the narrow family modus ponens. Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a collection of natural transformations in N^b , with two distinguished arguments.

- I^b has the **rough family MP** if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi \in \widetilde{T}_\Sigma \quad \text{and} \quad I_\Sigma^b[\phi, \psi] \leq \widetilde{T} \quad \text{imply} \quad \psi \in \widetilde{T}_\Sigma;$$

- I^b has the **narrow family MP** if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{and} \quad I_\Sigma^b[\phi, \psi] \leq T \quad \text{imply} \quad \psi \in T_\Sigma.$$

As with all preceding properties, the rough and narrow family MP turn out to be identical properties.

Lemma 1217 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b \subseteq N^b$ a family of natural transformations in N^b , with two distinguished arguments. I^b has the rough family MP if and only if it has the narrow family MP.*

Proof: The proof again follows along the lines of the proof of Lemma 1214, but we describe it also in detail.

Suppose, first, that I^b has the rough family MP and let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq T$. Again, by hypothesis, $\widetilde{T} = T$, whence, we get $\phi \in \widetilde{T}_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq \widetilde{T}$. Thus, by rough family MP, we get that $\psi \in \widetilde{T}_\Sigma$, i.e., $\psi \in T_\Sigma$. Thus, I^b has the narrow family MP.

Assume, conversely, that I^b has the narrow family MP and consider $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in \widetilde{T}_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq \widetilde{T}$. Since $\widetilde{T} \in \text{ThFam}^\sharp(\mathcal{I})$, we may apply narrow family MP to conclude that $\psi \in \widetilde{T}_\Sigma$. This proves that I^b has the rough family MP. ■

We say that $\mathcal{I}$ is **syntactically roughly/narrowly family monotone** if there exists $I^b \subseteq N^b$, with two distinguished arguments, such that I^b satisfies:

- narrow family reflexivity;
- narrow family transitivity;
- narrow family compatibility; and
- narrow family MP.

In that case, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic rough/narrow family monotonicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically narrowly family monotone π -institution, with witnessing transformations I^b , then $I^b(T)$ is a congruence system on $\mathbf{F}$ compatible with T , for all $T \in \text{ThFam}^\sharp(\mathcal{I})$. This forms a “narrow” analog of Proposition 790.

Proposition 1218 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations I^b , then, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$ compatible with T .*

Proof: The proof follows along the lines of the proof of Proposition 790. So we give an outline. Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$.

The narrow family reflexivity of I^b ensures that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. The fact that $\overleftrightarrow{I^b}$ is the symmetrization of I^b ensures that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$ implies that $\langle \psi, \phi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. The narrow family transitivity of I^b guarantees that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$ imply $\langle \phi, \chi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$.

Suppose, next, that $\sigma^b \in N^b$, $\vec{\phi}, \vec{\psi} \in \mathbf{SEN}^b(\Sigma)$. Then, the narrow family compatibility of I^b ensures that, if, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$, then $\langle \sigma_{\Sigma}^b(\vec{\phi}), \sigma_{\Sigma}^b(\vec{\psi}) \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. Thus, $\overleftrightarrow{I^b}(T)$ is a congruence family on $\mathbf{F}$. However, by Lemma 93, $\overleftrightarrow{I^b}(T)$ is a relation system on $\mathbf{F}$. Hence, $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$.

It only remains to show that $\overleftrightarrow{I^b}(T)$ is compatible with T . Assume that $\phi \in T_{\Sigma}$ and $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. Since $I^b \subseteq \overrightarrow{I^b}$, we get, by the narrow family MP of I^b , that $\psi \in T_{\Sigma}$. Thus, $\overleftrightarrow{I^b}(T)$ is also compatible with T . ■

Proposition 1218 shows that $\overleftrightarrow{I^b}$ defines Leibniz congruence systems of theory families in $\text{ThFam}^{\sharp}(\mathcal{I})$. Following similar terminology adopted in Chapter 14, we say that I^b **roughly** or **narrowly defines Leibniz congruence systems** of theory families in $\mathcal{I}$ if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$,

$$\overleftrightarrow{I^b}(T) = \Omega(T).$$

Then, in what is an analog of Corollary 791, we obtain

Corollary 1219 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations I^b , then I^b narrowly defines Leibniz congruence systems of theory families in $\mathcal{I}$.*

Proof: By Proposition 1218 and Corollary 98. ■

Corollary 1219 allows establishing the fact that syntactic narrow family monotonicity implies (semantic) narrow family monotonicity. This forms an analog of Theorem 792.

Theorem 1220 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly family monotone, then it is narrowly family monotone.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly family monotone with witnessing transformations I^b . Let $T, T' \in \text{ThFam}^{\sharp}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{aligned} \Omega(T) &= \overleftarrow{I^b}(T) \quad (\text{by Corollary 1219}) \\ &\leq \overleftarrow{I^b}(T') \quad (\text{by Lemma 94}) \\ &= \Omega(T'). \quad (\text{by Corollary 1219}) \end{aligned}$$

Thus, $\mathcal{I}$ is narrowly family monotone. ■

We now introduce the notion of the rough/narrow reflexive core of a π -institution $\mathcal{I}$ in a way analogous to the reflexive core, which was introduced in Chapter 11. Its introduction will enable us to provide a characterization of the syntactical narrow family monotonicity property and to establish a relationship between this property and its semantic counterpart.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- The **rough reflexive core** of $\mathcal{I}$ is the collection

$$\begin{aligned} \widetilde{R}^{\mathcal{I}} = \{ \rho^b \in N^b : & (\forall T \in \text{ThFam}(\mathcal{I})) (\forall \Sigma \in |\mathbf{Sign}^b|) \\ & (\forall \phi \in \mathbf{SEN}^b(\Sigma)) (\rho_{\Sigma}^b[\phi, \phi] \leq \widetilde{T}) \}; \end{aligned}$$

- The **narrow reflexive core** of $\mathcal{I}$ is the collection

$$\begin{aligned} R^{\mathcal{I}^{\sharp}} = \{ \rho^b \in N^b : & (\forall T \in \text{ThFam}^{\sharp}(\mathcal{I})) (\forall \Sigma \in |\mathbf{Sign}^b|) \\ & (\forall \phi \in \mathbf{SEN}^b(\Sigma)) (\rho_{\Sigma}^b[\phi, \phi] \leq T) \}. \end{aligned}$$

These two notions are identical, as shown in the following proposition, and this justifies the usage of the terms rough and narrow reflexive core interchangeably in this context.

Proposition 1221 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $\widetilde{R}^{\mathcal{I}} = R^{\mathcal{I}^{\sharp}}$.*

Proof: On the one hand, if $\rho^b \in \widetilde{R}^{\mathcal{I}}$, $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, then, by the definition of the rough reflexive core, $\rho_{\Sigma}^b[\phi, \phi] \leq \widetilde{T} = T$, where the equality follows from the assumption that $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. This shows that $\rho^b \in R^{\mathcal{I}^{\sharp}}$. On the other hand, if $\rho^b \in R^{\mathcal{I}^{\sharp}}$, $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, then, since $\widetilde{T} \in \text{ThFam}^{\sharp}(\mathcal{I})$, we get by the definition of $R^{\mathcal{I}^{\sharp}}$, $\rho_{\Sigma}^b[\phi, \phi] \leq \widetilde{T}$. This shows that $\rho^b \in \widetilde{R}^{\mathcal{I}}$. ■

Given any theory family in $\text{ThFam}^{\sharp}(\mathcal{I})$, the relation system $\overleftarrow{R^{\mathcal{I}^{\sharp}}}(T)$ is a reflexive relation system on $\mathbf{F}$. This forms an analog of Lemma 773.

Lemma 1222 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a reflexive relation system on $\mathbf{F}$.*

Proof: Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. By Lemma 93, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a relation system on $\mathbf{F}$. For reflexivity, let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. By the definition of the narrow reflexive core, $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \phi] \leq T$. Thus, $\langle \phi, \phi \rangle \in \overleftarrow{R}^{\mathcal{I}^{\sharp}}_{\Sigma}(T)$ and, therefore, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is reflexive. ■

As in Lemma 775, it may also be established that $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a symmetric relation system on $\mathbf{F}$, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$.

Lemma 1223 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a symmetric relation system on $\mathbf{F}$.*

Proof: Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. Again, Lemma 93 shows that $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a relation system. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}^{\sharp}}_{\Sigma}(T)$. Equivalently, $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$. Consider any $\rho^b \in R^{\mathcal{I}^{\sharp}}$. By the definition of $R^{\mathcal{I}^{\sharp}}$, we get that $\overline{\rho^b} \in R^{\mathcal{I}^{\sharp}}$. Therefore, by the hypothesis, $\overline{\rho^b}_{\Sigma}[\phi, \psi] \leq T$. But this gives $\rho^b_{\Sigma}[\psi, \phi] \leq T$. Since this holds for all $\rho^b \in R^{\mathcal{I}^{\sharp}}$, we conclude that $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\psi, \phi] \leq T$. Hence, $\langle \psi, \phi \rangle \in \overleftarrow{R}^{\mathcal{I}^{\sharp}}_{\Sigma}(T)$. Therefore, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ is a symmetric relation system on $\mathbf{F}$. ■

Continuing the study of sequence of properties of $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$, we show that, for all theory families $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ has the compatibility property in $\mathbf{F}$.

Lemma 1224 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}^{\sharp}}(T)$ has the compatibility property in $\mathbf{F}$.*

Proof: Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. We rely on Corollary 12. Let $\sigma^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ is in N^b , $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}^{\sharp}}_{\Sigma}(T)$ or, equivalently, $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$. Let $\rho^b : (\mathbf{SEN}^b)^n \rightarrow \mathbf{SEN}^b$ be arbitrary in $R^{\mathcal{I}^{\sharp}}$. We consider the natural transformation $\rho'^b : (\mathbf{SEN}^b)^{n+k} \rightarrow \mathbf{SEN}^b$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\zeta, \eta, \vec{\chi}, \vec{\xi} \in \mathbf{SEN}^b(\Sigma)$, by

$$\rho'_{\Sigma}(\zeta, \eta, \vec{\chi}, \vec{\xi}) = \rho_{\Sigma}^b(\sigma_{\Sigma}^b(\zeta, \vec{\chi}), \sigma_{\Sigma}^b(\eta, \vec{\chi}), \vec{\xi}).$$

Note that, since $\sigma^b \in N^b$, $\rho^b \in N^b$ and

$$\begin{aligned} \rho'^b &= \rho^b \circ \langle \sigma^b \circ \langle p^{n+k,0}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \sigma^b \circ \langle p^{n+k,1}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \\ &\quad p^{n+k,k+1}, \dots, p^{n+k,n+k-1} \rangle, \end{aligned}$$

we get that $\rho'^b \in N^b$. Moreover, for all $T' \in \text{ThFam}^{\mathcal{I}}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\zeta, \vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \rho'_\Sigma(\zeta, \zeta, \vec{\chi}, \vec{\xi}) &= \rho'_\Sigma(\sigma_\Sigma^b(\zeta, \vec{\chi}), \sigma_\Sigma^b(\zeta, \vec{\chi}), \vec{\xi}) \quad (\text{by definition of } \rho'^b) \\ &\in T'_\Sigma. \quad (\text{since } \rho^b \in R^{\mathcal{I}^\sharp}). \end{aligned}$$

Thus, by the definition of the narrow reflexive core, we get that $\rho'^b \in R^{\mathcal{I}^\sharp}$.

Now since $\rho^b \in R^{\mathcal{I}^\sharp}$ and, by hypothesis, $R^{\mathcal{I}^\sharp}_\Sigma[\phi, \psi] \leq T$, we get, in particular, that, for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi}, \vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\rho^b_{\Sigma'}(\sigma^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma^b_{\Sigma'}(\text{SEN}^b(f)(\psi), \vec{\chi}), \vec{\xi}) \in T_{\Sigma'}.$$

Hence, a fortiori, for all $\vec{\chi} \in \text{SEN}^b(\Sigma)$, $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\rho^b_{\Sigma'}(\text{SEN}^b(f)(\sigma^b_\Sigma(\phi, \vec{\chi})), \text{SEN}^b(f)(\sigma^b_\Sigma(\psi, \vec{\chi})), \vec{\xi}) \in T_{\Sigma'}.$$

This proves that

$$\rho^b_\Sigma[\sigma^b_\Sigma(\phi, \vec{\chi}), \sigma^b_\Sigma(\psi, \vec{\chi})] \leq T.$$

Since this holds for all $\rho^b \in R^{\mathcal{I}^\sharp}$, we get that $R^{\mathcal{I}^\sharp}_\Sigma[\sigma^b_\Sigma(\phi, \vec{\chi}), \sigma^b_\Sigma(\psi, \vec{\chi})] \leq T$ or, equivalently, $\langle \sigma^b_\Sigma(\phi, \vec{\chi}), \sigma^b_\Sigma(\psi, \vec{\chi}) \rangle \in \overleftarrow{R^{\mathcal{I}^\sharp}_\Sigma}(T)$. Therefore, $\overleftarrow{R^{\mathcal{I}^\sharp}}(T)$ has the congruence compatibility property in $\mathbf{F}$. ■

We now show, in an analog of Theorem 799, that possession of the narrow family modus ponens by the narrow reflexive core intrinsically characterizes syntactic narrow family monotonicity. We start by showing that possession of the narrow family MP by the narrow reflexive core is necessary for syntactic narrow family monotonicity. This forms an analog of Theorem 796.

Theorem 1225 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly family monotone, then $R^{\mathcal{I}^\sharp}$ has the narrow family MP.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly family monotone with witnessing transformations I^b . Since, by definition, I^b is narrowly family reflexive, we get, by definition of $R^{\mathcal{I}^\sharp}$, $I^b \subseteq R^{\mathcal{I}^\sharp}$. Thus, since I^b has narrow family MP in $\mathcal{I}$, we get that, a fortiori, $R^{\mathcal{I}^\sharp}$ also satisfies the narrow family MP. ■

Possession of narrow family MP by $R^{\mathcal{I}^\sharp}$ implies that $R^{\mathcal{I}^\sharp}$ has the narrow family transitivity in $\mathcal{I}$. This proposition forms an analog of Proposition 797.

Proposition 1226 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^\sharp}$ has the narrow family MP, then it also has the narrow family transitivity in $\mathcal{I}$.*

Proof: Suppose that $R^{\mathcal{I}^\sharp}$ has the narrow family MP and let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftarrow{R^{\mathcal{I}^\sharp}_\Sigma}(T)$. This means that $R^{\mathcal{I}^\sharp}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}^\sharp}_\Sigma[\psi, \chi] \leq T$. Then, by Lemma 1224, we get that, for all $\rho^b \in R^{\mathcal{I}^\sharp}$, and all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$R^{\mathcal{I}^\sharp}_{\Sigma'}[\rho^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), \vec{\xi}), \rho^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\chi), \vec{\xi})] \leq T.$$

But, by hypothesis, $R^{\mathcal{I}^\sharp}_\Sigma[\phi, \psi] \leq T$ and $R^{\mathcal{I}^\sharp}$ has the narrow family MP. Therefore, for all $\rho^b \in R^{\mathcal{I}^\sharp}$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\rho^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'},$$

i.e., $R^{\mathcal{I}^\sharp}_\Sigma[\phi, \chi] \leq T$. This shows $\langle \phi, \chi \rangle \in \overleftarrow{R^{\mathcal{I}^\sharp}_\Sigma}(T)$ and, hence, $R^{\mathcal{I}^\sharp}$ is narrowly family transitive in $\mathcal{I}$. ■

We are now ready to show a converse of Theorem 1225, i.e., that possession of the narrow family MP by $R^{\mathcal{I}^\sharp}$ suffices to establish the syntactic narrow family monotonicity of $\mathcal{I}$, since, in that case, $R^{\mathcal{I}^\sharp}$ serves as a family of witnessing transformations. The following constitutes an analog of Theorem 798.

Theorem 1227 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^\sharp}$ has the narrow family MP, then $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations $R^{\mathcal{I}^\sharp}$.*

Proof: By Lemma 1222, $R^{\mathcal{I}^\sharp}$ is narrowly family reflexive in $\mathcal{I}$. By Lemma 1223, $R^{\mathcal{I}^\sharp}$ is narrowly family symmetric in $\mathcal{I}$. By hypothesis and Proposition 1226, it is narrowly family transitive in $\mathcal{I}$. By Lemma 1224, it has the narrow family compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the narrow family MP in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations $R^{\mathcal{I}^\sharp}$. ■

Theorems 1225 and 1227 provide the promised characterization of syntactic narrow family monotonicity in terms of the narrow family MP of the narrow reflexive core.

$$\begin{array}{ccc} \mathcal{I} \text{ is Syntactically Narrow} & \longleftrightarrow & R^{\mathcal{I}^\sharp} \text{ has Narrow Family} \\ \text{Family Monotone} & & \text{Modus Ponens} \end{array}.$$

Theorem 1228 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly family monotone if and only if $R^{\mathcal{I}^\sharp}$ has the narrow family MP in $\mathcal{I}$.*

Proof: Theorem 1225 gives the “only if” and the “if” is by Theorem 1227.

■

A related alternative characterization asserts that syntactic narrow family monotonicity amounts to the narrow definability of Leibniz congruence systems of theory families by the narrow reflexive core. This result forms an analog of Theorem 801.

$$\begin{array}{ccc} \mathcal{I} \text{ is Syntactically Narrow} & \longleftrightarrow & R^{\mathcal{I}\sharp} \text{ Narrowly Defines Leibniz Congruence Systems of Theory Families} \\ \text{Family Monotone} & & \end{array}$$

Theorem 1229 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly family monotone if and only if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{R^{\mathcal{I}\sharp}}(T).$$

Proof: If $\mathcal{I}$ is syntactically narrowly family monotone, then, by Theorem 1225, $R^{\mathcal{I}\sharp}$ has the narrow family MP in $\mathcal{I}$. Thus, by Theorem 1227, $R^{\mathcal{I}\sharp}$ is a family of witnessing transformations for the syntactic narrow family monotonicity of $\mathcal{I}$. Thus, by Corollary 1219, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Omega(T) = \overleftarrow{R^{\mathcal{I}\sharp}}(T)$.

Suppose, conversely, that the displayed condition holds. Then $R^{\mathcal{I}\sharp}$ is narrowly family reflexive, narrowly family transitive and has the narrow family compatibility property and the narrow family MP. Hence, it constitutes a collection of witnessing transformations and, therefore, $\mathcal{I}$ is syntactically narrowly family monotone. ■

In the case of syntactic protoalgebraicity, in Chapter 11, it was shown that the property that separates syntactic protoalgebraicity from protoalgebraicity is the Leibniz compatibility property with respect to the theory family generated by the reflexive core, i.e., the property that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi])).$$

The task of characterizing those π -institutions that are syntactically narrowly family monotone among those that are narrowly family monotone is more involved. The additional complications arise from the fact that the class of theory families $\text{ThFam}^\sharp(\mathcal{I})$ may not be, in general, closed under (signature-wise) intersections and, hence, may not possess a least element. Therefore, to pinpoint syntactic narrow family monotonicity inside the class of narrow family monotone π -institutions, we need to devise a suitable analog of the Leibniz compatibility property with respect to the theory family generated by the narrow reflexive core.

To introduce this analog and to understand how it comes about and how it extends the Leibniz property, we interject a small discussion. Recall that a π -institution $\mathcal{I}$ is *protoalgebraic* if its Leibniz operator is monotone on theory families. Recall, also, that its reflexive core $R^{\mathcal{I}}$ is said to be *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])).$$

If a π -institution is protoalgebraic and has a Leibniz reflexive core, then it satisfies the global family modus ponens. This was shown in Chapter 11 using the following method. Considering $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_{\Sigma}$ and $R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$, we get:

- $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]))$ first, by applying the Leibniz property;
- $\Omega(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])) \leq \Omega(T)$, by applying the hypothesis that $R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T$ and the postulated protoalgebraicity of $\mathcal{I}$.

However, in case of narrow family monotonicity, the plausibility of $R_{\Sigma}^{\mathcal{I}}[\phi, \psi]$ having some empty components makes it likely that, in the second stage, narrow family monotonicity may not be applicable to ensure the inclusion $\Omega(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])) \leq \Omega(T)$.

An obvious remedy is to restrict attention to those π -institutions in which $C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi]) \in \text{ThFam}^{\sharp}(\mathcal{I})$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, and leave the Leibniz property unaltered. A more relaxed approach is to assume that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, the poset

$$[R_{\Sigma}^{\mathcal{I}}[\phi, \psi]] := \{T \in \text{ThFam}^{\sharp}(\mathcal{I}) : R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T\}$$

satisfies the descending chain condition and to postulate that every minimal element $T \in [R_{\Sigma}^{\mathcal{I}}[\phi, \psi]]$ satisfies $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- For $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, define

$$[R_{\Sigma}^{\mathcal{I}}[\phi, \psi]] := \{T \in \text{ThFam}^{\sharp}(\mathcal{I}) : R_{\Sigma}^{\mathcal{I}}[\phi, \psi] \leq T\};$$

- For $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\mathcal{I}$ is called **$\langle \Sigma, \phi, \psi \rangle$ -reflexively covered** if, for every theory family $T \in [R_{\Sigma}^{\mathcal{I}}[\phi, \psi]]$, there exists minimal $T' \in [R_{\Sigma}^{\mathcal{I}}[\phi, \psi]]$, such that $T' \leq T$;
- $\mathcal{I}$ is called **reflexively covered** if it is $\langle \Sigma, \phi, \psi \rangle$ -reflexively covered, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$.

Given $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, we write

$$\min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$$

for the collection of minimal elements in $[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow reflexive core $R^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T).$$

We show, in an analog of Proposition 785, that, if $R^{\mathcal{I}^{\sharp}}$ has the narrow family MP, then it is Leibniz. In fact, the proof demonstrates that, under the narrow family MP, a stronger property than that of being Leibniz holds; more precisely, we get that for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T).$$

Proposition 1230 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ has the narrow family MP, then for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$.*

Proof: Suppose $R^{\mathcal{I}^{\sharp}}$ has the narrow family MP and let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$. To verify that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$, we use Theorem 19. Let $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\bar{\chi} \in \text{SEN}^b(\Sigma')$, such that $\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) \in T_{\Sigma'}$. Since $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, by Lemma 1224,

$$R_{\Sigma'}^{\mathcal{I}^{\sharp}}[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi})] \leq T.$$

Thus, since, by hypothesis, $R^{\mathcal{I}^{\sharp}}$ has the narrow family MP, we obtain

$$\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi}) \in T_{\Sigma'}.$$

By symmetry, we conclude that, for all $\sigma^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\bar{\chi} \in \text{SEN}^b(\Sigma')$,

$$\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi}) \in T_{\Sigma'}.$$

Hence, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(T)$ and, therefore, $R^{\mathcal{I}^{\sharp}}$ is Leibniz. $\blacksquare$

Corollary 1231 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ has the narrow family MP, then it is Leibniz.*

Proof: Directly by Proposition 1230. ■

In the opposite direction, when dealing with reflexively covered π -institutions, we may show that narrow family monotonicity combined with the Leibniz property of the narrow reflexive core imply that the narrow reflexive core has the narrow family modus ponens in $\mathcal{I}$.

Proposition 1232 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a reflexively covered, narrowly family monotone π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^\sharp}$ is Leibniz, then it has the narrow family MP in $\mathcal{I}$.*

Proof: Let $\mathcal{I}$ be a reflexively covered π -institution. Suppose that $\mathcal{I}$ is narrowly family monotone and that $R^{\mathcal{I}^\sharp}$ is Leibniz. Let $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $R_\Sigma^{\mathcal{I}^\sharp}[\phi, \psi] \leq T$. Since $\mathcal{I}$ is reflexively covered, there exists $T' \in \min[R_\Sigma^{\mathcal{I}^\sharp}[\phi, \psi]]$, such that $T' \leq T$. Now we have

$$\begin{aligned} \langle \phi, \psi \rangle &\in \Omega_\Sigma(T') \quad (\text{since } R^{\mathcal{I}^\sharp} \text{ is Leibniz and } T' \in \min[R_\Sigma^{\mathcal{I}^\sharp}[\phi, \psi]]) \\ &\subseteq \Omega_\Sigma(T). \quad (\text{since } T' \leq T \text{ and } \mathcal{I} \text{ is narrowly family monotone}) \end{aligned}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T , that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}^\sharp}$ has the narrow family MP in $\mathcal{I}$. ■

Thus, at least for reflexively covered π -institutions, it is possible to show that the class of syntactically narrowly monotone ones inside the class of the narrowly monotone ones can be characterized exactly by the Leibniz property of the narrow reflexive core. This forms a partial analog of Theorem 805 in the narrow context.

Theorem 1233 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a reflexively covered π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly family monotone if and only if it is narrowly family monotone and has a Leibniz narrow reflexive core.*

Proof: Let $\mathcal{I}$ be a reflexively covered π -institution.

Suppose, first, that $\mathcal{I}$ is syntactically narrowly family monotone. By Theorem 1220, it is narrowly family monotone. Moreover, by Theorem 1225, its narrow reflexive core has the narrow family MP. Hence, by Corollary 1231, its narrow reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is narrowly family monotone with a Leibniz narrow reflexive core. Then, by Proposition 1232, its narrow reflexive core has the narrow family MP and, therefore, by Theorem 1227, $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations $R^{\mathcal{I}^\sharp}$. ■

We leave here as an open problem discovering a characterization along the lines of Theorem 1233, without the restriction that the π -institution in question be reflexively covered.

15.3 Syntactic Narrow System Monotonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 7 that $\mathcal{I}$ is *narrowly system monotone* if, for all $T, T' \in \text{ThSys}^{\sharp}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

In this section, in analogy with Section 15.2, we introduce and study a syntactic analog of this concept.

First, the concepts of narrow system reflexivity, narrow system symmetry, narrow system transitivity, narrow system compatibility and narrow system modus ponens can all be relativized to $\text{ThSys}^{\sharp}(\mathcal{I})$.

Let, as above, $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Moreover, suppose that $I^b \subseteq N^b$ is a collection of natural transformations in N^b , with two distinguished arguments.

- I^b is **narrowly system reflexive** if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \phi] \leq T;$$

- I^b is **narrowly system symmetric** if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \leq T \quad \text{implies} \quad I_{\Sigma}^b[\psi, \phi] \leq T;$$

- I^b is **narrowly system transitive** if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \mathbf{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \cup I_{\Sigma}^b[\psi, \chi] \leq T \quad \text{implies} \quad I_{\Sigma}^b[\phi, \chi] \leq T;$$

- I^b is **narrowly system compatible** if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, all $\sigma^b \in N^b$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \mathbf{SEN}^b(\Sigma)$,

$$\bigcup_{i < k} \vec{I}_{\Sigma}^b[\phi_i, \psi_i] \leq T \quad \text{implies} \quad I_{\Sigma}^b[\sigma_{\Sigma}^b(\vec{\phi}), \sigma_{\Sigma}^b(\vec{\psi})] \leq T;$$

- I^b has the **narrow system MP** if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi \in T_{\Sigma} \quad \text{and} \quad I_{\Sigma}^b[\phi, \psi] \leq T \quad \text{imply} \quad \psi \in T_{\Sigma}.$$

We say that $\mathcal{I}$ is **syntactically narrowly system monotone** if there exists $I^b \subseteq N^b$, with two distinguished arguments, such that I^b satisfies:

- narrow system reflexivity;
- narrow system transitivity;
- narrow system compatibility; and
- narrow system MP.

In that case, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic narrow system monotonicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically narrowly system monotone π -institution, with witnessing transformations I^b , then $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$ compatible with T , for all $T \in \text{ThSys}^\sharp(\mathcal{I})$. This forms a system analog of Proposition 1218.

Proposition 1234 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations I^b , then, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$ compatible with T .*

Proof: The proof is similar to that of Proposition 1218. Let $T \in \text{ThSys}^\sharp(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$. The narrow system reflexivity of I^b ensures that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. The fact that $\overleftrightarrow{I^b}$ is the symmetrization of I^b ensures that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$ implies that $\langle \psi, \phi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. The narrow system transitivity of I^b guarantees that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$ imply $\langle \phi, \chi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$.

Suppose, next, that $\sigma^b \in N^b$, $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$. Then, the narrow system compatibility of I^b ensures that, if, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$, then $\langle \sigma^b_\Sigma(\vec{\phi}), \sigma^b_\Sigma(\vec{\psi}) \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. Thus, $\overleftrightarrow{I^b}(T)$ is a congruence family on $\mathbf{F}$. However, by Lemma 93, $\overleftrightarrow{I^b}(T)$ is a relation system on $\mathbf{F}$. Hence, $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$.

It only remains to show that $\overleftrightarrow{I^b}(T)$ is compatible with T . Assume that $\phi \in T_\Sigma$ and $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_\Sigma(T)$. Since $I^b \subseteq \overleftrightarrow{I^b}$, we get, by the narrow system MP of I^b , that $\psi \in T_\Sigma$. Thus, $\overleftrightarrow{I^b}(T)$ is also compatible with T . $\blacksquare$

Proposition 1234 shows that $\overleftrightarrow{I^b}$ defines Leibniz congruence systems of theory systems in $\text{ThSys}^\sharp(\mathcal{I})$. Again, following terminology adopted in Section

15.2, we say that I^b **narrowly defines Leibniz congruence systems** of theory systems in $\mathcal{I}$ if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$,

$$\overleftrightarrow{I^b}(T) = \Omega(T).$$

Then, in what is an analog of Corollary 1219, we obtain

Corollary 1235 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrow system monotone, with witnessing transformations I^b , then I^b narrowly defines Leibniz congruence systems of theory systems in $\mathcal{I}$.*

Proof: By Proposition 1234 and Corollary 98. ■

Corollary 1235 shows that syntactic narrow system monotonicity implies (semantic) narrow system monotonicity. This forms an analog of Theorem 1220.

Theorem 1236 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrow system monotone, then it is narrowly system monotone.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrow system monotone with witnessing transformations I^b . Let $T, T' \in \text{ThSys}^{\sharp}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{aligned} \Omega(T) &= \overleftrightarrow{I^b}(T) \quad (\text{by Corollary 1235}) \\ &\leq \overleftrightarrow{I^b}(T') \quad (\text{by Lemma 94}) \\ &= \Omega(T'). \quad (\text{by Corollary 1235}) \end{aligned}$$

Thus, $\mathcal{I}$ is narrowly system monotone. ■

We now introduce the notion of the *narrow system reflexive core* of a π -institution $\mathcal{I}$ in a way analogous to the narrow reflexive core, which was introduced in Section 15.2. Its introduction will enable us to provide a characterization of the syntactic narrow system monotonicity property and to establish a relationship between this property and its semantic counterpart.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The **narrow system reflexive core** of $\mathcal{I}$ is the collection

$$R^{\mathcal{I}s} = \{ \rho^b \in N^b : (\forall T \in \text{ThSys}^{\sharp}(\mathcal{I})) (\forall \Sigma \in |\mathbf{Sign}^b|) (\forall \phi \in \mathbf{SEN}^b(\Sigma)) (\rho_{\Sigma}^b[\phi, \phi] \leq T) \}.$$

Given any theory system in $\text{ThSys}^{\sharp}(\mathcal{I})$, the relation system $\overleftarrow{R^{\mathcal{I}s}}(T)$ is a reflexive relation system on $\mathbf{F}$. This forms an analog of Lemma 1222.

Lemma 1237 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}s}(T)$ is a reflexive relation system on $\mathbf{F}$.*

Proof: Let $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$. By Lemma 93, $\overleftarrow{R}^{\mathcal{I}s}(T)$ is a relation system on $\mathbf{F}$. For reflexivity, let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. By the definition of the narrow system reflexive core, $R_{\Sigma}^{\mathcal{I}s}[\phi, \phi] \leq T$. Thus, $\langle \phi, \phi \rangle \in \overleftarrow{R}^{\mathcal{I}s}_{\Sigma}(T)$ and, therefore, $\overleftarrow{R}^{\mathcal{I}s}(T)$ is reflexive. ■

As in Lemma 1223, we establish that $\overleftarrow{R}^{\mathcal{I}s}(T)$ is a symmetric relation system on $\mathbf{F}$, for all $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$.

Lemma 1238 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}s}(T)$ is a symmetric relation system on $\mathbf{F}$.*

Proof: Let $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$. Again, Lemma 93 shows that $\overleftarrow{R}^{\mathcal{I}s}(T)$ is a relation system. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}s}_{\Sigma}(T)$. Equivalently, $R_{\Sigma}^{\mathcal{I}s}[\phi, \psi] \leq T$. Consider any $\rho^b \in R^{\mathcal{I}s}$. By the definition of $R^{\mathcal{I}s}$, we get that $\overline{\rho^b} \in R^{\mathcal{I}s}$. Therefore, by the hypothesis, $\overline{\rho^b}_{\Sigma}[\phi, \psi] \leq T$. But this gives $\rho^b_{\Sigma}[\psi, \phi] \leq T$. Since this holds for all $\rho^b \in R^{\mathcal{I}s}$, we conclude that $R_{\Sigma}^{\mathcal{I}s}[\psi, \phi] \leq T$. Hence, $\langle \psi, \phi \rangle \in \overleftarrow{R}^{\mathcal{I}s}_{\Sigma}(T)$. Therefore, $\overleftarrow{R}^{\mathcal{I}s}(T)$ is a symmetric relation system on $\mathbf{F}$. ■

We now show that, for all theory systems $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}s}(T)$ has the compatibility property in $\mathbf{F}$. This forms an analog of Lemma 1224.

Lemma 1239 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then, for all $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$, $\overleftarrow{R}^{\mathcal{I}s}(T)$ has the compatibility property in $\mathbf{F}$.*

Proof: Let $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$. We rely on Corollary 12. Let $\sigma^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ is in N^b , $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle \in \overleftarrow{R}^{\mathcal{I}s}_{\Sigma}(T)$ or, equivalently, $R_{\Sigma}^{\mathcal{I}s}[\phi, \psi] \leq T$. Let $\rho^b : (\mathbf{SEN}^b)^n \rightarrow \mathbf{SEN}^b$ be arbitrary in $R^{\mathcal{I}s}$. We consider the natural transformation $\rho'^b : (\mathbf{SEN}^b)^{n+k} \rightarrow \mathbf{SEN}^b$, defined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\zeta, \eta, \vec{\chi}, \vec{\xi} \in \mathbf{SEN}^b(\Sigma)$, by

$$\rho'^b_{\Sigma}(\zeta, \eta, \vec{\chi}, \vec{\xi}) = \rho^b_{\Sigma}(\sigma^b_{\Sigma}(\zeta, \vec{\chi}), \sigma^b_{\Sigma}(\eta, \vec{\xi}), \vec{\xi}).$$

Note that, since $\sigma^b \in N^b$, $\rho^b \in N^b$ and

$$\begin{aligned} \rho'^b &= \rho^b \circ \langle \sigma^b \circ \langle p^{n+k,0}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \sigma^b \circ \langle p^{n+k,1}, p^{n+k,2}, \dots, p^{n+k,k} \rangle, \\ &\quad p^{n+k,k+1}, \dots, p^{n+k,n+k-1} \rangle \rangle, \end{aligned}$$

we get that $\rho'^b \in N^b$. Moreover, for all $T' \in \text{ThSys}^b(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$, $\zeta, \bar{\chi}, \bar{\xi} \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \rho'^b(\zeta, \zeta, \bar{\chi}, \bar{\xi}) &= \rho_{\Sigma}^b(\sigma_{\Sigma}^b(\zeta, \bar{\chi}), \sigma_{\Sigma}^b(\zeta, \bar{\chi}), \bar{\xi}) \quad (\text{by definition of } \rho'^b) \\ &\in T'_{\Sigma}. \quad (\text{since } \rho^b \in R^{\mathcal{I}s}). \end{aligned}$$

Thus, by the definition of the narrow system reflexive core, we get that $\rho'^b \in R^{\mathcal{I}s}$.

Now since $\rho'^b \in R^{\mathcal{I}s}$ and, by hypothesis, $R_{\Sigma}^{\mathcal{I}s}[\phi, \psi] \leq T$, we get, in particular, that, for all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\bar{\chi}, \bar{\xi} \in \text{SEN}^b(\Sigma')$,

$$\rho_{\Sigma'}^b(\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi}), \bar{\xi}) \in T_{\Sigma'}.$$

Hence, a fortiori, for all $\bar{\chi} \in \text{SEN}^b(\Sigma)$, $\bar{\xi} \in \text{SEN}^b(\Sigma')$,

$$\rho_{\Sigma'}^b(\text{SEN}^b(f)(\sigma_{\Sigma}^b(\phi, \bar{\chi})), \text{SEN}^b(f)(\sigma_{\Sigma}^b(\psi, \bar{\chi})), \bar{\xi}) \in T_{\Sigma'}.$$

This proves that

$$\rho_{\Sigma}^b[\sigma_{\Sigma}^b(\phi, \bar{\chi}), \sigma_{\Sigma}^b(\psi, \bar{\chi})] \leq T.$$

Since this holds for all $\rho^b \in R^{\mathcal{I}s}$, we get that $R_{\Sigma}^{\mathcal{I}s}[\sigma_{\Sigma}^b(\phi, \bar{\chi}), \sigma_{\Sigma}^b(\psi, \bar{\chi})] \leq T$ or, equivalently, $\langle \sigma_{\Sigma}^b(\phi, \bar{\chi}), \sigma_{\Sigma}^b(\psi, \bar{\chi}) \rangle \in \overleftarrow{R^{\mathcal{I}s}}_{\Sigma}(T)$. Therefore, $\overleftarrow{R^{\mathcal{I}s}}(T)$ has the congruence compatibility property in $\mathbf{F}$. ■

We now show, in an analog of Theorem 1228, that possession of the narrow system modus ponens by the narrow system reflexive core intrinsically characterizes syntactic narrow system monotonicity. We start by showing that possession of the narrow system MP by the narrow system reflexive core is necessary for syntactic narrow system monotonicity. This forms an analog of Theorem 1225.

Theorem 1240 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly system monotone, then $R^{\mathcal{I}s}$ has the narrow system MP.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly system monotone with witnessing transformations I^b . Since, by definition, I^b is narrowly system reflexive, we get, by definition of $R^{\mathcal{I}s}$, $I^b \subseteq R^{\mathcal{I}s}$. Thus, since I^b has the narrow system MP in $\mathcal{I}$, we get that, a fortiori, $R^{\mathcal{I}s}$ also satisfies the narrow system MP. ■

If $R^{\mathcal{I}s}$ has the narrow system MP, then it has the narrow system transitivity in $\mathcal{I}$. This proposition forms an analog of Proposition 1226.

Proposition 1241 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}s}$ has the narrow system MP, then it also has the narrow system transitivity in $\mathcal{I}$.*

Proof: Suppose that $R^{\mathcal{I}s}$ has the narrow system MP and let $T \in \text{ThSys}^{\downarrow}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftarrow{R^{\mathcal{I}s}}_{\Sigma}(T)$. This means that $R^{\mathcal{I}s}_{\Sigma}[\phi, \psi] \leq T$ and $R^{\mathcal{I}s}_{\Sigma}[\psi, \chi] \leq T$. Then, by Lemma 1239, we get that, for all $\rho^b \in R^{\mathcal{I}s}$, and all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\xi \in \text{SEN}^b(\Sigma')$,

$$R^{\mathcal{I}s}_{\Sigma'}[\rho^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\psi), \vec{\xi}), \rho^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\chi), \vec{\xi})] \leq T.$$

But, by hypothesis, $R^{\mathcal{I}s}_{\Sigma}[\phi, \psi] \leq T$ and $R^{\mathcal{I}s}$ has the narrow system MP. Therefore, for all $\rho^b \in R^{\mathcal{I}s}$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \text{SEN}^b(\Sigma')$,

$$\rho^b_{\Sigma'}(\text{SEN}^b(f)(\phi), \text{SEN}^b(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'},$$

i.e., $R^{\mathcal{I}s}_{\Sigma}[\phi, \chi] \leq T$. This shows $\langle \phi, \chi \rangle \in \overleftarrow{R^{\mathcal{I}s}}_{\Sigma}(T)$ and, hence, $R^{\mathcal{I}s}$ is narrowly system transitive in $\mathcal{I}$. ■

We are now ready to show a converse of Theorem 1240, i.e., that possession of the narrow system MP by $R^{\mathcal{I}s}$ suffices to establish the syntactic narrow system monotonicity of $\mathcal{I}$, since, in that case, $R^{\mathcal{I}s}$ serves as a family of witnessing transformations. The following constitutes an analog of Theorem 1227.

Theorem 1242 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}s}$ has the narrow system MP, then $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations $R^{\mathcal{I}s}$.*

Proof: By Lemma 1237, $R^{\mathcal{I}s}$ is narrowly system reflexive in $\mathcal{I}$. By Lemma 1238, $R^{\mathcal{I}s}$ is narrowly system symmetric in $\mathcal{I}$. By hypothesis and Proposition 1241, it is narrowly system transitive in $\mathcal{I}$. By Lemma 1239, it has the narrow system compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the narrow system MP in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations $R^{\mathcal{I}s}$. ■

Theorems 1240 and 1242 provide the promised characterization of syntactic narrow system monotonicity in terms of the narrow system MP of the narrow system reflexive core.

$$\begin{array}{ccc} \mathcal{I} \text{ is Syntactically Narrow} & \longleftrightarrow & R^{\mathcal{I}s} \text{ has Narrow System} \\ \text{System Monotone} & & \text{Modus Ponens} \end{array}.$$

Theorem 1243 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly system monotone if and only if $R^{\mathcal{I}s}$ has the narrow system MP in $\mathcal{I}$.*

Proof: Theorem 1240 gives the “only if” and the “if” is by Theorem 1242.

■

A related alternative characterization asserts that syntactic narrow system monotonicity amounts to the narrow definability of Leibniz congruence systems of theory systems by the narrow system reflexive core. This result forms an analog of Theorem 1229.

$$\begin{array}{ccc} \mathcal{I} \text{ is Syntactically Narrow} & \longleftrightarrow & R^{\mathcal{I}s} \text{ Narrowly Defines Leibniz Congruence Systems of Theory Systems} \\ \text{System Monotone} & & \end{array}$$

Theorem 1244 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly system monotone if and only if, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$,*

$$\Omega(T) = \overleftarrow{R^{\mathcal{I}s}}(T).$$

Proof: If $\mathcal{I}$ is syntactically narrowly system monotone, then, by Theorem 1240, $R^{\mathcal{I}s}$ has the narrow system MP in $\mathcal{I}$. Thus, by Theorem 1242, $R^{\mathcal{I}s}$ is a family of witnessing transformations for the syntactic narrow system monotonicity of $\mathcal{I}$. Thus, by Corollary 1235, for all $T \in \text{ThSys}^{\sharp}(\mathcal{I})$, $\Omega(T) = \overleftarrow{R^{\mathcal{I}s}}(T)$.

Suppose, conversely, that the displayed condition holds. Then $R^{\mathcal{I}s}$ is narrowly system reflexive, narrowly system transitive and has the narrow system compatibility property and the narrow system MP. Hence, it constitutes a collection of witnessing transformations and, therefore, $\mathcal{I}$ is syntactically narrowly system monotone. ■

To prove an analog of Theorem 1233, which, in a certain restricted sense characterizes syntactic narrow family monotonicity inside the class of narrow family monotone π -institutions, we create a suitable analog of the Leibniz compatibility property with respect to the theory family generated by the narrow system reflexive core. Once more, the difficulty in this case, similarly with that described in some detail in Section 15.2, arises from the fact that $\text{ThSys}^{\sharp}(\mathcal{I})$ may not be, in general, closed under signature-wise intersections.

To introduce this analog and to understand how it comes about and how it extends the Leibniz property, we elaborate further on the relevant discussion initiated in Section 15.2. Recall that a π -institution $\mathcal{I}$ is *prealgebraic* if its Leibniz operator is monotone on theory systems. Recall, also, once more, that its reflexive core $R^{\mathcal{I}}$ is said to be *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])).$$

If a π -institution is prealgebraic and has a Leibniz reflexive core, then it satisfies the global system modus ponens. This was shown in Chapter 11

using the following method. Considering $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $R_\Sigma^\mathcal{I}[\phi, \psi] \leq T$, we get:

- $\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi]))$ first, by applying the Leibniz property;
- $\Omega(C(R_\Sigma^\mathcal{I}[\phi, \psi])) \leq \Omega(T)$, by applying the hypothesis that $R_\Sigma^\mathcal{I}[\phi, \psi] \leq T$ and the postulated prealgebraicity of $\mathcal{I}$ and observing at the same time that $C(R_\Sigma^\mathcal{I}[\phi, \psi]) \in \text{ThSys}(\mathcal{I})$, since $R_\Sigma^\mathcal{I}[\phi, \psi]$ is a sentence system.

However, in case of narrow system monotonicity, the plausibility of $R_\Sigma^{\mathcal{I}s}[\phi, \psi]$ having some empty components makes it likely that, in the second stage, narrow system monotonicity may not be applicable to ensure the inclusion $\Omega(C(R_\Sigma^{\mathcal{I}s}[\phi, \psi])) \leq \Omega(T)$. To deal with this plausibility, we assume, in a similar way as before, that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, the poset

$$[R_\Sigma^{\mathcal{I}s}[\phi, \psi]] := \{T \in \text{ThSys}^{\neq}(\mathcal{I}) : R_\Sigma^{\mathcal{I}s}[\phi, \psi] \leq T\}$$

satisfies the descending chain condition and to postulate that every minimal element $T \in [R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$ satisfies $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- For $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, define

$$[R_\Sigma^{\mathcal{I}s}[\phi, \psi]] := \{T \in \text{ThSys}^{\neq}(\mathcal{I}) : R_\Sigma^{\mathcal{I}s}[\phi, \psi] \leq T\};$$

- For $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\mathcal{I}$ is called **$\langle \Sigma, \phi, \psi \rangle$ -system reflexively covered** if, for every theory system $T \in [R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$, there exists minimal $T' \in [R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$, such that $T' \leq T$;
- $\mathcal{I}$ is called **system reflexively covered** if it is $\langle \Sigma, \phi, \psi \rangle$ -system reflexively covered, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$.

Given $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, we write

$$\min[R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$$

for the collection of minimal elements in $[R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow system reflexive core $R^{\mathcal{I}s}$ of $\mathcal{I}$ is **Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in \min[R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

We show, in an analog of Proposition 1230, that, if $R^{\mathcal{I}s}$ has the narrow system MP, then it is Leibniz. In fact, the proof demonstrates that, under the narrow system MP, a stronger property than that of being Leibniz holds; more concretely, that for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in [R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$ (and not only for $T \in \min[R_\Sigma^{\mathcal{I}s}[\phi, \psi]]$),

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

Proposition 1245 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}s}$ has the narrow system MP, then for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$ and all $T \in [R^{\mathcal{I}s}_\Sigma[\phi, \psi]]$, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$.*

Proof: Suppose $R^{\mathcal{I}s}$ has the narrow system MP and let $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$. To verify that $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, we use Theorem 19. Let $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$, such that $\sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}) \in T_{\Sigma'}$. Since $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, by Lemma 1239,

$$R^{\mathcal{I}s}_{\Sigma'}[\sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}), \sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi})] \leq T.$$

Thus, since, by hypothesis, $R^{\mathcal{I}s}$ has the narrow system MP, we obtain

$$\sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

By symmetry, we conclude that, for all $\sigma^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$,

$$\sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\phi), \vec{\chi}) \in T_{\Sigma'} \quad \text{iff} \quad \sigma^b_{\Sigma'}(\mathbf{SEN}^b(f)(\psi), \vec{\chi}) \in T_{\Sigma'}.$$

Hence, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. ■

Corollary 1246 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}s}$ has the narrow system MP, then it is Leibniz.*

Proof: Directly by Proposition 1245. ■

In the opposite direction, when dealing with system reflexively covered π -institutions, we may show that narrow system monotonicity combined with the Leibniz property of the narrow system reflexive core imply that the narrow system reflexive core has the narrow system modus ponens in $\mathcal{I}$. The following proposition forms an analog of Proposition 1232 in the system context.

Proposition 1247 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a system reflexively covered, narrowly system monotone π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}s}$ is Leibniz, then it has the narrow system MP in $\mathcal{I}$.*

Proof: Let $\mathcal{I}$ be a system reflexively covered π -institution. Suppose that $\mathcal{I}$ is narrowly system monotone and that $R^{\mathcal{I}s}$ is Leibniz. Let $T \in \text{ThSys}^{\mathcal{I}}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$ and $R^{\mathcal{I}s}_\Sigma[\phi, \psi] \leq T$. Since $\mathcal{I}$ is system reflexively covered, there exists $T' \in \min[R^{\mathcal{I}s}_\Sigma[\phi, \psi]]$, such that $T' \leq T$. Now we have

$$\begin{aligned} \langle \phi, \psi \rangle &\in \Omega_\Sigma(T') \quad (\text{since } R^{\mathcal{I}s} \text{ is Leibniz and } T' \in \min[R^{\mathcal{I}s}_\Sigma[\phi, \psi]]) \\ &\subseteq \Omega_\Sigma(T). \quad (\text{since } T' \leq T \text{ and } \mathcal{I} \text{ is narrowly system monotone}) \end{aligned}$$

Therefore, since $\phi \in T_\Sigma$, we get, by the compatibility of $\Omega(T)$ with T , that $\psi \in T_\Sigma$. We conclude that $R^{\mathcal{I}s}$ has the narrow system MP in $\mathcal{I}$. ■

Thus, at least for system reflexively covered π -institutions, it is possible to show that the class of syntactically narrowly system monotone ones inside the class of the narrowly system monotone ones can be characterized exactly by the Leibniz property of the narrow system reflexive core. This forms a partial analog of Theorem 1233.

Theorem 1248 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a system reflexively covered π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly system monotone if and only if it is narrowly system monotone and has a Leibniz narrow system reflexive core.*

Proof: Let $\mathcal{I}$ be a system reflexively covered π -institution.

Suppose, first, that $\mathcal{I}$ is syntactically narrowly system monotone. By Theorem 1236, it is narrowly system monotone. Moreover, by Theorem 1240, its narrow system reflexive core has the narrow system MP. Hence, by Corollary 1246, its narrow system reflexive core is Leibniz.

Suppose, conversely, that $\mathcal{I}$ is narrowly system monotone with a Leibniz narrow system reflexive core. Then, by Proposition 1247, its narrow system reflexive core has the narrow system MP and, therefore, by Theorem 1242, $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations $R^{\mathcal{I}s}$. ■

We leave here as an open problem generalizing Theorem 1233 so that it is applicable to arbitrary π -institutions and not merely to those that are system reflexively covered.

15.4 Syntactic Narrow Right Monotonicity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $I^b \subseteq N^b$ a collection of natural transformations in N^b , with two distinguished arguments. Recall from Proposition 99, that, for all $T \in \text{SenFam}(\mathbf{F})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$I_\Sigma^b[\phi, \psi] \leq T \quad \text{iff} \quad I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T}. \quad (15.1)$$

Let, now, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. We may attempt to define “syntactic narrow left monotonicity” as the existence of a collection $I^b \subseteq N^b$, with two distinguished arguments, such that, for all $T \in \text{ThFam}^\ell(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T} \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

Because of the the preceding remark, however, this condition would amount exactly to defining syntactic narrow family monotonicity. On the other hand,

syntactic narrow system monotonicity is equivalent, again based on the remark above, to asserting the existence of $I^b \subseteq N^b$, with two distinguished arguments, such that, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, with $\overleftarrow{T} \in \text{ThSys}^{\sharp}(\mathcal{I})$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \leq T \quad \text{iff} \quad \langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T}).$$

If we drop the restriction that $\overleftarrow{T}$ be in $\text{ThSys}^{\sharp}(\mathcal{I})$, thus allowing the condition above to be imposed on the wider class of all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, we obtain a concept slightly more general than syntactic narrow system monotonicity, which we term *syntactic narrow right monotonicity*. We study this notion in more detail in this section, following the study of syntactic narrow family (and system) monotonicity, carried out in Section 15.2 (and 15.3, respectively) of the chapter.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 7 that $\mathcal{I}$ is *narrowly right monotone* if, for all $T, T' \in \text{ThFam}^{\sharp}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(\overleftarrow{T}) \leq \Omega(\overleftarrow{T'}).$$

In this section, following the work on syntactic narrow family monotonicity of Section 15.2, we introduce and study a syntactic analog of narrow right monotonicity.

First, the concepts of narrow system reflexivity, narrow system symmetry, narrow system transitivity, narrow system compatibility and narrow system modus ponens are recast to accommodate theory systems that arise by applying the arrow operator $\overleftarrow{}$ on theory families in $\text{ThFam}^{\sharp}(\mathcal{I})$. Note that such theory systems include, of course, all theory systems in $\text{ThSys}^{\sharp}(\mathcal{I})$, since these arise by applying the arrow operator on themselves.

Let, as above, $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Moreover, suppose that $I^b \subseteq N^b$ is a collection of natural transformations in N^b , with two distinguished arguments.

- I^b is **narrowly right reflexive** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \phi] \leq \overleftarrow{T};$$

- I^b is **narrowly right symmetric** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \leq \overleftarrow{T} \quad \text{implies} \quad I_{\Sigma}^b[\psi, \phi] \leq \overleftarrow{T};$$

- I^b is **narrowly right transitive** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$,

$$I_{\Sigma}^b[\phi, \psi] \cup I_{\Sigma}^b[\psi, \chi] \leq \overleftarrow{T} \quad \text{implies} \quad I_{\Sigma}^b[\phi, \chi] \leq \overleftarrow{T};$$

- I^b is **narrowly right compatible** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\sigma^b \in N^b$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$,

$$\bigcup_{i < k} \vec{I}^b_{\Sigma}[\phi_i, \psi_i] \leq \overleftarrow{T} \quad \text{implies} \quad I^b_{\Sigma}[\sigma^b_{\Sigma}(\vec{\phi}), \sigma^b_{\Sigma}(\vec{\psi})] \leq \overleftarrow{T};$$

- I^b has the **narrow right MP** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi \in \overleftarrow{T}_{\Sigma} \quad \text{and} \quad I^b_{\Sigma}[\phi, \psi] \leq \overleftarrow{T} \quad \text{imply} \quad \psi \in \overleftarrow{T}_{\Sigma}.$$

Note that, because of Equivalence (15.1), narrow right reflexivity, narrow right symmetry, narrow right transitivity and narrow right compatibility are equivalent, respectively, to narrow family reflexivity, narrow family symmetry, narrow family transitivity and narrow family compatibility. They are simply recast involving the arrow operator, but the change is inessential. On the other hand, narrow right modus ponens is an essentially different property than narrow family modus ponens and it is the critical property that differentiates syntactic narrow right monotonicity from syntactic narrow family monotonicity.

Note, also, that, based on Equivalence (15.1), for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$,

$$\overleftarrow{I}^b(T) = \overleftarrow{I}^b(\overleftarrow{T}).$$

We say that $\mathcal{I}$ is **syntactically narrowly right monotone** if there exists $I^b \subseteq N^b$, with two distinguished arguments, such that I^b satisfies:

- narrow right reflexivity;
- narrow right transitivity;
- narrow right compatibility; and
- narrow right MP.

In that case, we call I^b a **set of witnessing natural transformations**, or, more simply, **witnessing transformations** (of the syntactic narrow right monotonicity of $\mathcal{I}$).

It turns out that, if $\mathcal{I}$ is a syntactically narrowly right monotone π -institution, with witnessing transformations I^b , then $\overleftarrow{I}^b(T) \quad (:= \overleftarrow{I}^b(\overleftarrow{T}))$ is a congruence system on $\mathbf{F}$ compatible with $\overleftarrow{T}$, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. This forms a “right” analog of Proposition 1218.

Proposition 1249 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations I^b , then, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\overleftarrow{I}^b(T)$ is a congruence system on $\mathbf{F}$ compatible with $\overleftarrow{T}$.*

Proof: The proof is similar to that of Proposition 1218. Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$. The narrow right reflexivity of I^b ensures that $\langle \phi, \phi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. The fact that $\overleftrightarrow{I^b}$ is the symmetrization of I^b ensures that $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$ implies that $\langle \psi, \phi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. The narrow right transitivity of I^b guarantees that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$ imply $\langle \phi, \chi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$.

Suppose, next, that $\sigma^b \in N^b$, $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$. Then, the narrow right compatibility of I^b ensures that, if, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$, then $\langle \sigma^b_{\Sigma}(\vec{\phi}), \sigma^b_{\Sigma}(\vec{\psi}) \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. Thus, $\overleftrightarrow{I^b}(T)$ is a congruence family on $\mathbf{F}$. However, by Lemma 93, $\overleftrightarrow{I^b}(T)$ is a relation system on $\mathbf{F}$. Hence, $\overleftrightarrow{I^b}(T)$ is a congruence system on $\mathbf{F}$.

It only remains to show that $\overleftrightarrow{I^b}(T)$ is compatible with $\overleftarrow{T}$. Assume that $\phi \in \overleftarrow{T}_{\Sigma}$ and $\langle \phi, \psi \rangle \in \overleftrightarrow{I^b}_{\Sigma}(T)$. Since $I^b \subseteq \overleftrightarrow{I^b}$, we get, by the narrow right MP of I^b , that $\psi \in \overleftarrow{T}_{\Sigma}$. Thus, $\overleftrightarrow{I^b}(T)$ is also compatible with $\overleftarrow{T}$. ■

Proposition 1249 shows that $\overleftrightarrow{I^b}$ defines Leibniz congruence systems of those theory systems of the form $\overleftarrow{T}$, for $T \in \text{ThFam}^{\sharp}(\mathcal{I})$. We say that I^b **narrowly defines Leibniz congruence systems** of theory families in $\mathcal{I}$ **up to arrow** if, for all $T \in \text{ThFam}^{\sharp}(\mathcal{I})$,

$$\overleftrightarrow{I^b}(T) = \Omega(\overleftarrow{T}).$$

Then, in what is an analog of Corollary 1219, we obtain

Corollary 1250 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations I^b , then I^b narrowly defines Leibniz congruence systems of theory families in $\mathcal{I}$ up to arrow.*

Proof: By Proposition 1234 and Corollary 98. ■

This corollary has as immediate consequence the fact that syntactic narrow right monotonicity implies (semantic) narrow right monotonicity. This forms an analog of Theorem 1220.

Theorem 1251 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly right monotone, then it is narrowly right monotone.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly right monotone with witnessing transformations I^b . Let $T, T' \in \text{ThFam}^{\sharp}(\mathcal{I})$, such that $T \leq T'$. Then

$$\begin{aligned} \Omega(\overleftarrow{T}) &= \overleftarrow{I^b}(T) \quad (\text{by Corollary 1250}) \\ &\leq \overleftarrow{I^b}(T') \quad (\text{by Lemma 94}) \\ &= \Omega(\overleftarrow{T'}). \quad (\text{by Corollary 1250}) \end{aligned}$$

Thus, $\mathcal{I}$ is narrowly right monotone. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Section 15.2 that the *narrow reflexive core* of $\mathcal{I}$ is the collection

$$R^{\mathcal{I}^{\sharp}} = \{ \rho^b \in N^b : (\forall T \in \text{ThFam}^{\sharp}(\mathcal{I})) (\forall \Sigma \in |\mathbf{Sign}^b|) (\forall \phi \in \text{SEN}^b(\Sigma)) (\rho_{\Sigma}^b[\phi, \phi] \leq T) \}.$$

Recall, also, from Lemmas 1222, 1223 and 1224, that, given any theory family in $\text{ThFam}^{\sharp}(\mathcal{I})$, the relation system $\overleftarrow{R^{\mathcal{I}^{\sharp}}}(T)$ is a reflexive and symmetric relation system on $\mathbf{F}$ that has the (congruence) compatibility property in $\mathbf{F}$.

We now show, in an analog of Theorem 1228, that possession of the narrow right modus ponens by the narrow reflexive core intrinsically characterizes syntactic narrow right monotonicity. We start by showing that possession of the narrow right MP by the narrow reflexive core is necessary for syntactic narrow right monotonicity. This forms an analog of Theorem 1225.

Theorem 1252 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically narrowly right monotone, then $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP.*

Proof: Suppose that $\mathcal{I}$ is syntactically narrowly right monotone with witnessing transformations I^b . Since, by definition, I^b is narrowly right reflexive, which is equivalent to being narrowly family reflexive, we get, by definition of $R^{\mathcal{I}^{\sharp}}$, $I^b \subseteq R^{\mathcal{I}^{\sharp}}$. Thus, since I^b has the narrow right MP in $\mathcal{I}$, we get that, a fortiori, $R^{\mathcal{I}^{\sharp}}$ also satisfies the narrow right MP. $\blacksquare$

If $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, then it has the narrow right transitivity in $\mathcal{I}$. This proposition forms an analog of Proposition 1226.

Proposition 1253 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, then it also has the narrow right transitivity in $\mathcal{I}$.*

Proof: Suppose that $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP and let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi, \chi \in \text{SEN}^b(\Sigma)$, such that $\langle \phi, \psi \rangle, \langle \psi, \chi \rangle \in \overleftarrow{R^{\mathcal{I}^{\sharp}}}_{\Sigma}(T)$. This

means that $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$ and $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\psi, \chi] \leq T$. Then, by Lemma 1239, we get that, for all $\rho^b \in R^{\mathcal{I}^{\sharp}}$, and all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$R_{\Sigma'}^{\mathcal{I}^{\sharp}}[\rho_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\psi), \vec{\xi}), \rho_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\chi), \vec{\xi})] \leq T.$$

But, by hypothesis, $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$ and $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP. Therefore, for all $\rho^b \in R^{\mathcal{I}^{\sharp}}$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\xi} \in \mathbf{SEN}^b(\Sigma')$,

$$\rho_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \mathbf{SEN}^b(f)(\chi), \vec{\xi}) \subseteq T_{\Sigma'},$$

i.e., $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \chi] \leq T$. This shows $\langle \phi, \chi \rangle \in \overleftarrow{R^{\mathcal{I}^{\sharp}}}_{\Sigma}(T)$ and, hence, $R^{\mathcal{I}^{\sharp}}$ is narrowly right transitive in $\mathcal{I}$. ■

We are now ready to show a converse of Theorem 1252, i.e., that possession of the narrow right MP by $R^{\mathcal{I}^{\sharp}}$ suffices to establish the syntactic narrow right monotonicity of $\mathcal{I}$, since, in that case, $R^{\mathcal{I}^{\sharp}}$ serves as a family of witnessing transformations. The following constitutes an analog of Theorem 1227.

Theorem 1254 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, then $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations $R^{\mathcal{I}^{\sharp}}$.*

Proof: By Lemma 1222, $R^{\mathcal{I}^{\sharp}}$ is narrowly right reflexive in $\mathcal{I}$. By Lemma 1223, $R^{\mathcal{I}^{\sharp}}$ is narrowly right symmetric in $\mathcal{I}$. By hypothesis and Proposition 1253, it is narrowly right transitive in $\mathcal{I}$. By Lemma 1224 it has the narrow right compatibility property in $\mathcal{I}$. Finally, by hypothesis, it has the narrow right MP in $\mathcal{I}$. We conclude that $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations $R^{\mathcal{I}^{\sharp}}$. ■

Theorems 1252 and 1254 provide the promised characterization of syntactic narrow right monotonicity in terms of the narrow right MP of the narrow reflexive core.

$$\begin{array}{ccc} \mathcal{I} \text{ is Syntactically Narrow} & \longleftrightarrow & R^{\mathcal{I}^{\sharp}} \text{ has Narrow Right} \\ \text{Right Monotone} & & \text{Modus Ponens} \end{array} .$$

Theorem 1255 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly right monotone if and only if $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP in $\mathcal{I}$.*

Proof: Theorem 1252 gives the “only if” and the “if” is by Theorem 1254. ■

A related alternative characterization asserts that syntactic narrow right monotonicity amounts to the narrow definability of Leibniz congruence systems of theory families up to arrow by the narrow reflexive core. This result forms an analog of Theorem 1229.

$$\begin{array}{ccc} \mathcal{I} \text{ is Syntactically Narrow} & & R^{\mathcal{I}^\sharp} \text{ Narrowly Defines Leibniz} \\ \text{Right Monotone} & \longleftrightarrow & \text{Congruence Systems of Theory} \\ & & \text{Families up to Arrow} \end{array}$$

Theorem 1256 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly right monotone if and only if, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$,*

$$\Omega(\overleftarrow{T}) = \overleftarrow{R^{\mathcal{I}^\sharp}}(T).$$

Proof: If $\mathcal{I}$ is syntactically narrowly right monotone, then, by Theorem 1252, $R^{\mathcal{I}^\sharp}$ has the narrow right MP in $\mathcal{I}$. Thus, by Theorem 1254, $R^{\mathcal{I}^\sharp}$ is a family of witnessing transformations for the syntactic narrow right monotonicity of $\mathcal{I}$. Thus, by Corollary 1250, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, $\Omega(\overleftarrow{T}) = \overleftarrow{R^{\mathcal{I}^\sharp}}(T)$.

Suppose, conversely, that the displayed condition holds. Then $R^{\mathcal{I}^\sharp}$ is narrowly right reflexive, narrowly right transitive and has the narrow right compatibility property and the narrow right MP. Hence, it constitutes a collection of witnessing transformations and, therefore, $\mathcal{I}$ is syntactically narrowly right monotone. ■

To prove an analog of Theorem 1233, which, in a sense analogous to that seen for syntactic narrow family monotonicity, characterizes syntactic narrow right monotonicity inside the class of narrow right monotone π -institutions, we create a suitable analog of the Leibniz compatibility property with respect to the theory family generated by the narrow reflexive core. Once more, the difficulty in this case, similarly with that described in some detail in Section 15.2, arises from the fact that $\text{ThFam}^\sharp(\mathcal{I})$ may not be, in general, closed under signature-wise intersections.

To introduce this analog and to understand how it comes about and how it extends the Leibniz property, we reembark, once more, on a discussion initiated in Section 15.2 and revisit some of the points with relevance in treating the “right” case.

Recall, again, the definition of protoalgebraicity and the Leibniz property of the reflexive core of a π -institution. Also recall the method employed to show that, if a π -institution is protoalgebraic and has a Leibniz reflexive core, then it satisfies the global modus ponens, which is done by first applying the Leibniz property and then protoalgebraicity. However, in case of narrow right monotonicity, the plausibility of $R_\Sigma^{\mathcal{I}^\sharp}[\phi, \psi]$ having some empty components makes it likely that, when one attempts to apply narrow right monotonicity

in place of protoalgebraicity in the second stage of the argument outlined above, its application in order to derive the inclusion $\Omega(C(R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi])) \leq \Omega(\overleftarrow{T})$ may not be possible. To deal with this plausibility, we assume, in a similar way as before, that the π -institution under consideration is reflexively covered and postulate that every minimal element $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$ satisfies $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T})$, for every $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, recall the notation

$$[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]] := \{T \in \text{ThFam}^{\sharp}(\mathcal{I}) : R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T\}.$$

Recall, also, that $\mathcal{I}$ is said to be *reflexively covered* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, it is $\langle \Sigma, \phi, \psi \rangle$ -reflexively covered, i.e., for every theory family $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, there exists minimal $T' \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, such that $T' \leq T$. Recall, furthermore, that, given $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, we write $\min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$ for the collection of minimal elements in $[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that the narrow reflexive core $R^{\mathcal{I}^{\sharp}}$ of $\mathcal{I}$ is **right Leibniz** if, for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$,

$$\langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T}).$$

We show, in an analog of Proposition 1230, that, if $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, then it is right Leibniz. In fact, the proof demonstrates that, under the narrow right MP, a stronger property than that of being right Leibniz holds; more concretely, that for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$ (not only for $T \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$), $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T})$.

Proposition 1257 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, then for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi, \psi \in \text{SEN}^b(\Sigma)$ and all $T \in [R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T})$.*

Proof: Suppose $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP and let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$. To verify that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T})$, we use Theorem 19. Let $\sigma^b \in N^b$, $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\vec{\chi} \in \text{SEN}^b(\Sigma')$, such that $\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}) \in \overleftarrow{T}_{\Sigma'}$. Since $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, by Lemma 1224,

$$R_{\Sigma'}^{\mathcal{I}^{\sharp}}[\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \vec{\chi}), \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi})] \leq T.$$

Thus, since, by hypothesis, $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, we obtain

$$\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \vec{\chi}) \in \overleftarrow{T}_{\Sigma'}.$$

By symmetry, we conclude that, for all $\sigma^b \in N^b$, all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\bar{\chi} \in \mathbf{SEN}^b(\Sigma')$,

$$\sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \bar{\chi}) \in \overleftarrow{T}_{\Sigma'} \quad \text{iff} \quad \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \bar{\chi}) \in \overleftarrow{T}_{\Sigma'}.$$

Hence, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(\overleftarrow{T})$. ■

Corollary 1258 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP, then it is right Leibniz.*

Proof: Directly by Proposition 1257. ■

To prove a converse, we restrict attention to reflexively covered π -institutions. Inside this class, we may show that narrow right monotonicity combined with the right Leibniz property of the narrow reflexive core imply that the narrow reflexive core has the narrow right modus ponens in $\mathcal{I}$. The following proposition forms an analog of Propositions 1232 and 1247 in the “right” context.

Proposition 1259 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a reflexively covered, narrowly right monotone π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^{\sharp}}$ is right Leibniz, then it has the narrow right MP in $\mathcal{I}$.*

Proof: Let $\mathcal{I}$ be a reflexively covered π -institution. Suppose that $\mathcal{I}$ is narrowly right monotone and that $R^{\mathcal{I}^{\sharp}}$ is right Leibniz. Let $T \in \text{ThFam}^{\sharp}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in \overleftarrow{T}_{\Sigma}$ and $R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi] \leq T$. Since $\mathcal{I}$ is reflexively covered, there exists $T' \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]$, such that $T' \leq T$. Now we have

$$\begin{aligned} \langle \phi, \psi \rangle &\in \Omega_{\Sigma}(\overleftarrow{T'}) \quad (\text{since } R^{\mathcal{I}^{\sharp}} \text{ is right Leibniz and } T' \in \min[R_{\Sigma}^{\mathcal{I}^{\sharp}}[\phi, \psi]]) \\ &\subseteq \Omega_{\Sigma}(\overleftarrow{T}). \quad (\text{since } T' \leq T \text{ and } \mathcal{I} \text{ is narrowly right monotone}) \end{aligned}$$

Therefore, since $\phi \in \overleftarrow{T}_{\Sigma}$, we get, by the compatibility of $\Omega(\overleftarrow{T})$ with $\overleftarrow{T}$, that $\psi \in \overleftarrow{T}_{\Sigma}$. We conclude that $R^{\mathcal{I}^{\sharp}}$ has the narrow right MP in $\mathcal{I}$. ■

Thus, at least for reflexively covered π -institutions, it is possible to show that the class of syntactically narrowly right monotone ones inside the class of the narrowly right monotone ones can be characterized exactly by the right Leibniz property of the narrow reflexive core. This forms a partial analog of Theorems 1233 and 1248.

Theorem 1260 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a reflexively covered π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically narrowly right monotone if and only if it is narrowly right monotone and has a right Leibniz narrow reflexive core.*

Proof: Let $\mathcal{I}$ be a reflexively covered π -institution.

Suppose, first, that $\mathcal{I}$ is syntactically narrowly right monotone. By Theorem 1251, it is narrowly right monotone. By Theorem 1252, its narrow reflexive core has the narrow right MP. Hence, by Corollary 1258, its narrow reflexive core is right Leibniz.

Suppose, conversely, that $\mathcal{I}$ is narrowly right monotone with a right Leibniz narrow reflexive core. Then, by Proposition 1259, its narrow reflexive core has the narrow right MP and, therefore, by Theorem 1254, $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations $R^{\mathcal{I}^t}$. ■

An open problem, once more, is to provide a general intrinsic characterization, along the lines of Theorem 1260, applicable to arbitrary π -institutions and not only to those that are reflexively covered.

We conclude the section (and the chapter) by establishing some inclusions between the classes of π -institutions that were introduced in this chapter. More precisely, we show that each of syntactic narrow family monotonicity and syntactic narrow right monotonicity implies syntactic narrow system monotonicity.

Proposition 1261 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically narrowly family monotone, then it is syntactically narrowly system monotone;*
- (b) *If $\mathcal{I}$ is syntactically narrowly right monotone, then it is syntactically narrowly system monotone.*

Proof: We prove Part (a) in two different ways. This is instructive, since one proof is simply based on the relevant definitions and the other makes use of some of the results obtained in the various sections. Then we prove Part (b) in only one way, using the definitions.

Suppose $\mathcal{I}$ is syntactically narrowly family monotone, with witnessing transformations I^b . Then I^b is narrow family reflexive, narrow family transitive, has narrow family compatibility and satisfies the narrow family modus ponens. In particular I^b satisfies narrow system reflexivity, narrow system transitivity, narrow system compatibility and the narrow system modus ponens. Thus, by definition, $\mathcal{I}$ is syntactically narrowly system monotone, with witnessing transformations I^b .

We now give the second (indirect) proof. Suppose $\mathcal{I}$ is syntactically narrowly family monotone. Then, by Theorem 1228, the narrow reflexive core $R^{\mathcal{I}^t}$ has the narrow family modus ponens in $\mathcal{I}$. But, by definition, we have $R^{\mathcal{I}^t} \subseteq R^{\mathcal{I}^s}$. Thus, we get that the narrow system reflexive core has the narrow family modus ponens in $\mathcal{I}$. Hence, a fortiori, the narrow system reflexive core $R^{\mathcal{I}^s}$ has the narrow system modus ponens in $\mathcal{I}$. Therefore, by Theorem

1243, $\mathcal{I}$ is syntactically narrowly system monotone. This proof shows how one may use the two characterization theorems, Theorems 1228 and 1243, to proceed with statements concerning the two classes related.

For an elementary proof for Part (b), assume that $\mathcal{I}$ is syntactically narrowly right monotone, with witnessing transformations I^b . Then I^b has the narrow right reflexivity, narrow right transitivity, narrow right compatibility and narrow right modus ponens. The first three properties are equivalent to narrow family reflexivity, narrow family transitivity and narrow family compatibility, respectively, and, consequently, imply narrow system reflexivity, narrow system transitivity and narrow system compatibility, respectively. The narrow right modus ponens asserts that, for all $T \in \text{ThFam}^\sharp(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ, ψ , $\phi \in \overleftarrow{T}_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T}$ imply $\psi \in \overleftarrow{T}_\Sigma$. Since, for all $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{T} = T$, this implies that, for all $T \in \text{ThSys}^\sharp(\mathcal{I})$, all signatures Σ and all Σ -sentences ϕ, ψ , $\phi \in T_\Sigma$ and $I_\Sigma^b[\phi, \psi] \leq T$ imply $\psi \in T_\Sigma$. That is, I^b also satisfies the narrow system modus ponens. Hence, I^b is a collection of witnessing transformations for the syntactic narrow system monotonicity of $\mathcal{I}$ as well. ■

Proposition 1261 gives rise to the following syntactic narrow monotonicity subhierarchy.

Two examples are now in order to show that none of the arrows in the diagram collapse and, therefore, the hierarchy is exactly as shown. The first example gives a π -institution which is syntactically narrowly family monotone, but fails to be syntactically narrowly right monotone.

Example 1262 EXAMPLE NOT FOUND YET!

The second example gives a π -institution which is syntactically narrowly right monotone, but fails to be syntactically narrowly family monotone.

Example 1263 EXAMPLE NOT FOUND YET!

Chapter 16

The Syntactic Leibniz Hierarchy: Attic I

16.1 Introduction

In this chapter our goal is to develop a hierarchy analogous to the one developed in Chapter 8, but on the syntactic side. The key on the semantic side, developed in Chapter 8, was the property of regularity of a π -institution. The family version of the property asserts that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$, $\mathcal{I}$ is *family regular* if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad \langle \phi, \psi \rangle \in \Omega_\Sigma(T).$$

By combining this property with pre- or proto-algebraicity, on the one hand, and with the existence of theorems, on the other, which subsumes complete reflectivity, one obtains various classes in the regular (weak) (pre)algebraizability hierarchy, which were studied in some detail in Chapter 8.

Here, as our interest shifts to the syntactic side, the role played by of pre- and proto-algebraicity is assumed by syntactic pre- and proto-algebraicity, respectively, and the existence of theorems is replaced by the existence of natural theorems. By adding these features to regularity, one obtains the classes of the syntactically regularly (weakly) (pre)algebraizable π -institutions, which dominate, in general, the corresponding semantic classes. Roughly speaking, the hierarchy that we are aiming for here has the general shape depicted in the accompanying diagram. Of course various classes are present at each level, since the properties shown have various flavors, or versions, that may be used at each of the combinations depicted.

In Section 3.3, we studied the classes of prealgebraic and of protoalgebraic π -institutions. In Sections 11.2 and 11.3, we studied their syntactic counterparts, syntactically prealgebraic and syntactically protoalgebraic, π -institutions, respectively. In Section 5.4, we studied strengthenings of the semantic properties, obtaining the classes of preequivalential and equivalential

π -institutions, whereas in Sections 13.3 and 13.4, we looked at their syntactic counterparts, syntactically preequivalential and syntactically equivalential π -institutions. On the other hand, in Section 8.2, we studied semantic regularity and in Section 8.3, we studied assertionality. Section 16.2 will introduce the corresponding syntactic notion of regularity and Section 16.5 will deal with syntactic assertionality. In Sections 8.4, 8.5, 8.6 and 8.7, combining the basic semantic notions listed above, we obtained four classes close to the very top of the semantic algebraic hierarchy, namely those of regularly weakly prealgebraizable and regularly weakly algebraizable π -institutions and those of regularly prealgebraizable and of regularly algebraizable π -institutions. Using the syntactic analogs of those properties, we shall define syntactic analogs of these four classes. In Section 16.6, we get syntactically regularly weakly prealgebraizable π -institutions, in Section 16.7, syntactically regularly weakly algebraizable π -institutions and in Section 16.8, syntactically regularly prealgebraizable and syntactically regularly algebraizable π -institutions.

In Section 16.2, we study various versions of the regularity property of a collection I^b of natural transformations, with two distinguished arguments, in a π -institution $\mathcal{I}$. There are four apparently different ones, family, left, right and system regularity. E.g., we say that I^b is *family regular* in $\mathcal{I}$ if, for every theory family T , all signatures Σ and all Σ -sentences ϕ, ψ , $\phi, \psi \in T_\Sigma$ imply $I_\Sigma^b[\phi, \psi] \leq T$. It is shown that family and right regularity coincide, as do left and system regularity. So we fix the terms *family regularity* and *system regularity* for the two genuinely different regularity properties. Family regularity implies system regularity and these two coincide if the π -institution happens to be systemic. Finally, it is proven that these properties transfer from a π -institution $\mathcal{I}$ to all models of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

In Section 16.3, we combine the properties of syntactic pre/protoalgebraicity with those of regularity of the witnessing transformations to get the classes of syntactically regularly pre/protoalgebraic π -institutions. Since we have two versions of syntactic monotonicity (pre- and protoalgebraicity) and two versions of regularity of natural transformations, we obtain, a priori, four versions of syntactic regular pre/protoalgebraicity. These are termed *syntactic family regular protoalgebraicity*, *syntactic system regular protoalgebraicity*, *syntactic family regular prealgebraicity* and *syntactic system regular prealgebraicity*. E.g., we say that a π -institution $\mathcal{I}$ is *syntactically family regularly protoalgebraic* if it is syntactically protoalgebraic, with witnessing collection of natural transformations I^b , which is family regular in $\mathcal{I}$. Now recall from Section 8.2 the semantic regularity hierarchy, which consists of four properties, which are, enumerated from strongest to weakest, family regularity, right regularity, left regularity and system regularity. Connecting them to the present context, we show that, if a π -institution $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations I^b , then $\mathcal{I}$ is family regular if and only if I^b is family regular in $\mathcal{I}$ and it is left regular if and only if I^b is system

regular in $\mathcal{I}$. On the other hand, provided that $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b , then $\mathcal{I}$ is right regular if and only if I^b is family regular in $\mathcal{I}$ and it is system regular if and only if I^b is system regular in $\mathcal{I}$. These equivalences, together with the forms of the subhierarchies of syntactic pre/protoalgebraicity, family/system regularity of natural transformations and family/right/left/system regularity of π -institutions lead to the subhierarchy of syntactic regular pre/protoalgebraicity properties. This turns out to be a rhombus, with syntactic family regular protoalgebraicity at the top, syntactic family regular prealgebraicity and syntactic system regular protoalgebraicity below it and syntactic system regular prealgebraicity at the bottom. Besides identifying its shape, the section also provides some relationships between classes of the hierarchy and those syntactic classes lying right below it and, also, some relationships with their semantic counterparts. We then recall, also from Section 8.2, the three characterizations of regularity properties involving the Suszko operator. For a π -institution $\mathcal{I}$, $\mathcal{I}$ is family regular if and only if, for all signatures Σ and all Σ -sentences ϕ, ψ , $\langle \phi, \psi \rangle \in \tilde{\Omega}^{\mathcal{I}}(C(\phi, \psi))$. For left regularity, the condition is replaced by $\langle \phi, \psi \rangle \in \tilde{\Omega}^{\mathcal{I}}(\vec{C}(\phi, \psi))$, whereas for system regularity by $\langle \phi, \psi \rangle \in \hat{\Omega}^{\mathcal{I}}(\vec{C}(\phi, \psi))$. These characterizations enable us to obtain corresponding ones for family regularity of a collection of witnessing transformations in case of syntactic protoalgebraicity and for system regularity of witnessing transformations in case of syntactic prealgebraicity. E.g., if $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations I^b , then I^b is family regular if and only if, for all signatures Σ and all Σ -sentences ϕ, ψ , $\langle \phi, \psi \rangle \in \tilde{\Omega}^{\mathcal{I}}(C(\phi, \psi))$. The section ends with a transfer theorem asserting that all four versions of syntactic regular pre/protoalgebraicity transfer from a π -institution to all $\mathcal{I}$ -models of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

In Section 16.4, we upgrade syntactic pre- and protoalgebraicity to syntactic preequivalentiality and equivalentiality, respectively, and combining them, once more, with regularity properties of witnessing transformations, we get syntactic regular preequivalentiality and syntactic regular equivalentiality properties, respectively. We again obtain, a priori, four versions, *syntactic family regular equivalentiality*, *syntactic system regular equivalentiality*, *syntactic family regular preequivalentiality* and *syntactic system regular preequivalentiality*. E.g., we say that a π -institution $\mathcal{I}$ is *syntactically family regularly equivalential* if it is syntactically equivalential, with witnessing collection I^b of transformations, which is family regular in $\mathcal{I}$. If $\mathcal{I}$ is syntactically equivalential, with witnessing transformations I^b , then $\mathcal{I}$ is family regular if and only if I^b is family regular in $\mathcal{I}$ and $\mathcal{I}$ is left regular if and only if I^b is system regular in $\mathcal{I}$. Similarly, if $\mathcal{I}$ is syntactically preequivalential, then $\mathcal{I}$ is right regular if and only if I^b is family regular in $\mathcal{I}$ and $\mathcal{I}$ is system regular if and only if I^b is system regular in $\mathcal{I}$. The four classes of the hierarchy are stratified in a rhombus, with syntactic family regular equivalen-

tiality at the apex, syntactic family regular preequivalentiality and syntactic system regular equivalentiality below it and syntactic system regular preequivalentiality at the bottom. We detail how this subhierarchy is related to other syntactic properties lying right below it in the syntactic hierarchy. Further, we show that the rhombus of syntactic regular (pre)equivalentiality properties lies above (property by property) the rhombus of syntactic regular pre/protoalgebraicity properties, studied in Section 16.3. Similarly, with the case of syntactic pre/protoalgebraicity, we get that, under syntactic equivalentiality, the parameter free collection I^b of witnessing transformations is family regular in $\mathcal{I}$ if and only if, for all signatures Σ and all Σ -sentences ϕ, ψ , $\langle \phi, \psi \rangle \in \widehat{\Omega}^{\mathcal{I}}(C(\phi, \psi))$, while, under syntactic preequivalentiality, the parameter free collection of witnessing transformations I^b is system regular in $\mathcal{I}$ if and only if, for all signatures Σ and all Σ -sentences ϕ, ψ , $\langle \phi, \psi \rangle \in \widehat{\Omega}^{\mathcal{I}}(\vec{C}(\phi, \psi))$. This section also concludes with a theorem asserting that all four versions of syntactic regular (pre)equivalentiality properties transfer.

In Section 8.2, we introduced the four (semantic) regularity properties, ranging, in order from strongest to weakest, from family to right to left to system regularity. In Section 8.3, to those regularity properties was added the property of having theorems, which resulted into three classes of assertionality, family/right, left and system assertionality. These three classes were shown to dominate each the corresponding version of the complete reflectivity hierarchy. In Section 16.5, we replace existence of theorems by the stronger property of having natural theorems, studied in Section 14.7, thus obtaining the *syntactic assertionality* hierarchy. In fact, adding to (semantic) regularity the property of possessing natural theorems, allows replacing c-reflectivity by truth equationality, its syntactic counterpart, and this forms a strong motivation and justification for this move.

Since there are four regularity properties, we get, a priori, four classes of syntactic assertionality, syntactic family, left, right and system assertionality. However, as was the case with (semantic) assertionality, syntactic family and syntactic right assertionality coincide. Among the three different classes, syntactic family/right assertionality implies syntactic left assertionality, which, in turn, implies syntactic system assertionality. Additionally, syntactic left and syntactic system assertionality are identified if applied only to stable π -institutions and the whole hierarchy collapses to a single class if only systemic π -institutions are taken into account. By definition and the fact that possessing natural theorems implies having theorems, we get that each syntactic assertionality class dominates the corresponding semantic assertionality class. Based on previously obtained characterizations of the semantic assertionality classes, we obtain analogous characterizations of syntactic classes involving the Leibniz operator. More precisely, we get that a π -institution $\mathcal{I}$ is syntactically family assertional if and only if, for every theory family T , $T = \tau/\Omega(T)$, where τ is a natural theorem. In the

corresponding characterization for syntactic left assertional, the condition is replaced by $\overleftarrow{T} = \tau/\Omega(T)$, whereas for syntactic system assertional, the first condition involves quantification over theory systems rather than theory families. It is also shown that each of these three syntactic assertional classes lies above the corresponding truth equationality class, where, in each case, the witnessing equation of truth equationality is $\iota \approx \tau$, with ι the identity natural transformation and τ a (unary) natural theorem. The section closes with a transfer theorem to the effect that all syntactic assertional properties transfer from a π -institution $\mathcal{I}$ to all models of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

in Section 16.6, we combine syntactic prealgebraicity with the three versions of syntactic assertional to obtain *syntactic regular weak prealgebraizability* classes, abbreviated to syntactic RW prealgebraizability. We say that a π -institution $\mathcal{I}$ is *syntactically regularly weakly family prealgebraizable* (syntactically RWF prealgebraizable) if it is syntactically prealgebraic and syntactically family assertional. It is *syntactically regularly weakly left prealgebraizable* (syntactically RWL prealgebraizable) if it is syntactically prealgebraic and syntactically left assertional and it is *syntactically regularly weakly system prealgebraizable* (syntactically RWS prealgebraizable) if it is syntactically prealgebraic and syntactically system assertional. Because of the implications governing the syntactic assertional properties, described in Section 16.5, we obtain that syntactic RWF prealgebraizability implies syntactic RWL prealgebraizability, which implies syntactic RWS prealgebraizability.

As far as relationships with classes further down in the syntactic hierarchy go, we have that syntactic RWF prealgebraizability implies syntactic family regular protoalgebraicity and syntactic RWS prealgebraizability implies syntactic system regular prealgebraicity. Concerning relationships with classes in the syntactic assertional hierarchy, we get that, if $\mathcal{I}$ is syntactically RW family (left, system) prealgebraizable, then it is syntactically family (left, system, respectively) assertional. Still staying with relationships with other syntactically defined classes, we also have that each class in the syntactic RW prealgebraizability hierarchy dominates the corresponding class in the syntactic weak prealgebraizability hierarchy. As regards relationships with semantically defined classes, we obtain that each syntactic RW prealgebraizability class is contained in the corresponding regularly weak prealgebraizability class. Having, at least partially, placed the syntactic RW prealgebraizability subhierarchy relative to its surroundings, we show that all its three versions transfer. We end the section by providing some characterization/transfer theorems in terms of isomorphisms between lattices of theory families and of congruence systems and of definability of theory families via their Leibniz congruence systems. With the intent of merely giving a flavor, we describe the result for syntactic RWF prealgebraizability. It is equivalent to $\Omega : \text{ThFam}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ being an order isomorphism and

$\mathcal{I}$ having a Leibniz reflexive core and a natural theorem τ , such that, for all theory families T , $T = \tau/\Omega(T)$.

If we switch from syntactic prealgebraicity to syntactic protoalgebraicity and add versions of syntactic assertionality, we pass from syntactic RW prealgebraizability to *syntactic regular weak algebraizability* (syntactic RW algebraizability). This constitutes the focus of Section 16.7. However, as will be described shortly, this section may be seen as an addendum to Section 16.6, since its end result is adding one more class between the top and middle classes of the three class hierarchy studied in Section 16.6. We say that a π -institution is *syntactically regularly weakly family algebraizable* (syntactically RWF algebraizable) if it is syntactically protoalgebraic and syntactically family assertional. It is *syntactically regularly weakly left algebraizable* (syntactically RWL algebraizable) if it is syntactically protoalgebraic and syntactically left assertional and it is *syntactically regularly weakly system algebraizable* (syntactically RWS algebraizable) if it is syntactically protoalgebraic and syntactically system assertional. Family assertionality implies systemicity and, under systemicity, syntactic prealgebraicity coincides with syntactic protoalgebraicity. So we get that syntactic RWF prealgebraizability and syntactic RWF algebraizability are identical properties. Thus, the top two classes in the hierarchies of Sections 16.6 and 16.7 coincide. Even more, due to the fact that protoalgebraicity implies stability, syntactic RWL algebraizability turns out to be identical with syntactic RWS algebraizability. Hence the syntactic regular weak algebraizability hierarchy consists only of two classes and, when merged with the three class syntactic regular weak prealgebraizability hierarchy of Section 16.6, gives a total of four linearly ordered classes.

Returning to the relations between different subhierarchies from Section 16.6, and in light of this new form, we show that each of the four classes lies above the corresponding syntactic regular pre/protoalgebraicity class. A similar picture emerges in relation to syntactic assertionality properties. Moving to relations with classes up higher in the syntactic hierarchy, we see that each of the four syntactic regular weak (pre)algebraizability properties implies the corresponding syntactic weak (pre)algebraizability property. Turning to relationships of the four classes with corresponding classes in the semantic regular weak (pre)algebraizability hierarchy, we see that the latter are dominated by the corresponding ones in the former. This section also concludes, as does Section 16.6, with a transfer theorem for the new class, as well as with a characterization theorem involving mappings between lattices of theory families and of congruence systems. These results complete the picture already appearing at the end of Section 16.6 for three of the four classes in the combined hierarchy of the two sections.

In Sections 16.6 and 16.7, we established the syntactic regular weak (pre)algebraizability hierarchy, which arises by combining syntactic pre/protoalgebraicity with syntactic assertionality properties. If, instead of syntactic

pre/protoalgebraicity, syntactic (pre)equivalentiality is used, we get a hierarchy of four stronger classes, constituting the *syntactic regular (pre)algebraizability* subhierarchy. This is the main topic of Section 16.8. More precisely, if syntactic preequivalentiality is combined with syntactic family, syntactic left or syntactic system assertionality, we obtain *syntactic regular family*, *left* or *system prealgebraizability*, respectively. If, on the other hand, syntactic equivalentiality is combined with each of the three syntactic assertionality properties, we get the classes of *syntactically regularly family*, *left* or *system algebraizable* π -institutions. As with syntactic regular weak (pre)algebraizability, this apparent six class hierarchy collapses to a linear hierarchy of four properties, in order, from strongest to weakest, syntactic regular family algebraizability, syntactic regular system algebraizability, syntactic regular left prealgebraizability and syntactic regular system prealgebraizability. Each of these classes dominates a corresponding syntactic regular (pre)equivalentiality class. It is not difficult to see that each of the four classes lies above the corresponding syntactic regular weak (pre)algebraizability class and this yields, also, that it lies above the corresponding syntactic assertionality class. Further, each of the four classes lies above the corresponding syntactic (pre)algebraizability class. Compared with semantically defined classes, syntactic regular (pre)algebraizability classes dominate the corresponding regular (pre)algebraizability classes. The section ends with a transfer theorem and with characterization/transfer theorems using mappings between lattices of theory families and of congruence systems.

16.2 Regularity of Transformations

To prepare us for the main developments, we start by looking closely at the various versions of the regularity property of a family of natural transformations in a given π -institution.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Moreover, let $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ be a collection of natural transformations in N^b , having two distinguished arguments. We define the following properties:

- I^b has the **family regularity in $\mathcal{I}$** , or is **family regular in $\mathcal{I}$** , if, for all $T \in \text{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad I_\Sigma^b[\phi, \psi] \leq T;$$

- I^b has the **left regularity in $\mathcal{I}$** , or is **left regular in $\mathcal{I}$** , if, for all $T \in \text{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\phi, \psi \in \overleftarrow{T}_\Sigma \quad \text{implies} \quad I_\Sigma^b[\phi, \psi] \leq T;$$

- I^b has the **right regularity in $\mathcal{I}$** , or is **right regular in $\mathcal{I}$** , if, for all $T \in \text{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T};$$

- I^b has the **system regularity in $\mathcal{I}$** , or is **system regular in $\mathcal{I}$** , if, for all $T \in \text{ThSys}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi, \psi \in T_\Sigma \quad \text{implies} \quad I_\Sigma^b[\phi, \psi] \leq T.$$

Recalling that, by Proposition 99, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, we have

$$I_\Sigma^b[\phi, \psi] \leq T \quad \text{iff} \quad I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T},$$

it is easy to see that the four properties defined above collapse in pairs and, therefore, there are only two distinct ones.

Proposition 1264 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a collection of natural transformations in N^b , with two distinguished arguments.*

- (a) I^b is family regular in $\mathcal{I}$ if and only if it is right regular in $\mathcal{I}$;
- (b) I^b is system regular in $\mathcal{I}$ if and only if it is left regular in $\mathcal{I}$.

Proof: By Proposition 99, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, we have

$$I_\Sigma^b[\phi, \psi] \leq T \quad \text{iff} \quad I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T}.$$

Thus, taking into account the definitions of family and right regularity, the equivalence of Part (a) becomes clear. We turn now to Part (b).

Assume, first, that I^b is left regular in $\mathcal{I}$ and let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $T \in \text{ThSys}(\mathcal{I})$, $\overleftarrow{T} = T$, whence, by hypothesis, $\phi, \psi \in \overleftarrow{T}_\Sigma$. Thus, by left regularity, $I_\Sigma^b[\phi, \psi] \leq T$. This shows that I^b has the system regularity in $\mathcal{I}$.

Suppose, conversely, that I^b is system regular in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Since $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, we get, by system regularity, $I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T}$. Therefore, by Proposition 99, $I_\Sigma^b[\phi, \psi] \leq T$, showing that I^b has the left regularity in $\mathcal{I}$. ■

Based on Proposition 1264, we use the term **family regular** to refer to family/right regularity and the term **system regular** for system/left regularity. As far as the relation between these two distinct properties, it is straightforward to see that, as is typical with almost all properties studied in the monograph, system regularity is weaker than family regularity.

Proposition 1265 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a collection of natural transformations in N^b , having two distinguished arguments. If I^b is family regular in $\mathcal{I}$, then it is system regular in $\mathcal{I}$.*

Proof: This is clear from the definitions, since the condition defining system regularity is a specialization of that defining family regularity, where T is allowed to range over theory systems only. ■

Thus, the following hierarchy of regularity properties emerges.

It is also easy to see that, in case $\mathcal{I}$ is systemic, the two properties of being family and system regular are identical.

Proposition 1266 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a collection of natural transformations in N^b . If $\mathcal{I}$ is systemic, then I^b is system regular if and only if it is family regular in $\mathcal{I}$.*

Proof: If $\mathcal{I}$ is systemic, then $\text{ThFam}(\mathcal{I}) = \text{ThSys}(\mathcal{I})$, whence the two conditions defining family and system regularity are identical. ■

And it is not difficult to show that this hierarchy does not collapse in general.

Example 1267 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system defined as follows:*

- $\mathbf{Sign}^b$ is the category with the single object Σ and a single (non-identity) morphism $f : \Sigma \rightarrow \Sigma$, such that $f \circ f = f$;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is defined by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$ and $\mathbf{SEN}^b(f)(0) = 0$, $\mathbf{SEN}^b(f)(1) = 0$;
- N^b is the clone of natural transformations generated by the binary natural transformation $\sigma^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$, specified by

$$\sigma_\Sigma^b(x, y) = 0, \quad \text{for all } x, y \in \mathbf{SEN}^b(\Sigma).$$

Define the π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\emptyset, \{1\}, \{0, 1\}\}.$$

$\mathcal{I}$ has three theory families $\overline{\emptyset}$, $\{\{1\}\}$ and SEN^b , but only two theory systems, $\overline{\emptyset}$ and SEN^b . Consider $I^b = \{\sigma^b\}$. Since, the only theory systems are $\overline{\emptyset}$ and SEN^b , I^b is trivially system regular. On the other hand, for $T = \{\{1\}\}$, we get, $1 \in T_\Sigma$, but $I_\Sigma^b[1, 1] = \{\{0\}\} \not\leq \{\{1\}\}$, whence I^b is not family regular in $\mathcal{I}$.

We close the section by showing that the two versions of regularity transfer from the family I^b to I^A , for all $\mathcal{I}$ -gmatrix families $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$.

Proposition 1268 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ a collection of natural transformations in N^b , with two distinguished arguments.*

- (a) *I^b is family regular in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, I^A is family regular in $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$;*
- (b) *I^b is system regular in $\mathcal{I}$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, I^A is system regular in $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.*

Proof:

- (a) The “if” follows easily by considering the $\mathbf{F}$ -algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$ and recalling from Lemma 51 that $\text{FiFam}^\mathcal{I}(\mathcal{F}) = \text{ThFam}(\mathcal{I})$.

Assume, conversely, that I^b is family regular in $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$, $\Sigma \in |\text{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then, $\phi, \psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. By Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, whence, by the postulated family regularity of I^b in $\mathcal{I}$, we get that $I_\Sigma^b[\phi, \psi] \leq \alpha^{-1}(T)$. Thus, by Lemma 95, we get $I_{F(\Sigma)}^A[\alpha_\Sigma(\phi), \alpha_\Sigma(\psi)] \leq T$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that, for all $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$, all $\Sigma \in |\text{Sign}^b|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$, if $\phi, \psi \in T_\Sigma$, then $I_\Sigma^A[\phi, \psi] \leq T$. Therefore, I^A is family regular in $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

(b) This follows along very similar lines. ■

16.3 Syntactic Regular PreAlgebraicity

In the next result, we connect the property of regularity of a collection of natural transformations with the property of regularity of a π -institution $\mathcal{I}$, studied in Chapter 8. More specifically, we show that, in case the π -institution under consideration is syntactically pre- (proto-)algebraic with I^b a collection of witnessing transformations, then family (system) regularity of I^b is equivalent to $\mathcal{I}$ being family (system) regular. Since the combination of syntactic pre- and proto-algebraicity with regularity turns out to be an important property in its own right, we give it a name, partly inspired by the results that follow. Recall that there are two kinds of syntactic monotonicity, namely syntactic prealgebraicity and syntactic protoalgebraicity, and two kinds of regularity properties of collections of natural transformations, namely family regularity and system regularity. Thus, by combining syntactic monotonicity properties with regularity properties, we obtain, a priori, four versions.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is said to be **syntactically family regularly protoalgebraic** if it is syntactically protoalgebraic, with a witnessing collection I^b of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly protoalgebraic** if it is syntactically protoalgebraic, with a witnessing collection I^b of transformations, which is system regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically family regularly prealgebraic** if it is syntactically prealgebraic, with a witnessing collection I^b of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly prealgebraic** if it is syntactically prealgebraic, with a witnessing collection I^b of transformations, which is system regular in $\mathcal{I}$.

The definitions are partially justified by the following propositions that relate them to the semantic notions of family, right, left and system regularity.

Proposition 1269 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution based on $\mathbf{F}$, with witnessing transformations $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$.*

(a) $\mathcal{I}$ is family regular if and only if I^b is family regular in $\mathcal{I}$;

(b) $\mathcal{I}$ is left regular if and only if I^b is system regular in $\mathcal{I}$.

Proof: Let $\mathcal{I}$ be a syntactically protoalgebraic π -institution, with witnessing transformations I^b .

(a) This part is easy to see, since, by syntactic protoalgebraicity, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(T) \quad \text{iff} \quad I_\Sigma^b[\phi, \psi] \leq T.$$

(b) Suppose, first, that $\mathcal{I}$ is left regular and let $T \in \text{ThSys}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Since $T \in \text{ThSys}(\mathcal{I})$, $\phi, \psi \in \overleftarrow{T}_\Sigma$. By the left regularity of $\mathcal{I}$, we get $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$, whence, by syntactic protoalgebraicity, $I_\Sigma^b[\phi, \psi] \leq T$. This shows that I^b is system regular in $\mathcal{I}$.

Assume, conversely, that I^b is system regular in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi, \psi \in \overleftarrow{T}_\Sigma$. Then, since $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, by the system regularity of I^b , $I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T} \leq T$, whence, by syntactic protoalgebraicity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is left regular. ■

Proposition 1270 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically prealgebraic π -institution based on $\mathbf{F}$, with witnessing transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$.*

(a) $\mathcal{I}$ is right regular if and only if I^b is family regular in $\mathcal{I}$;

(b) $\mathcal{I}$ is system regular if and only if I^b is system regular in $\mathcal{I}$.

Proof: Let $\mathcal{I}$ be a syntactically prealgebraic π -institution, with witnessing transformations I^b .

(a) Suppose, first, that $\mathcal{I}$ is right regular and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. By the right regularity of $\mathcal{I}$, we get $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$, whence, since $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, we get, by syntactic prealgebraicity, $I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T} \leq T$. This shows that I^b is family regular in $\mathcal{I}$.

Assume, conversely, that I^b is family regular in $\mathcal{I}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\phi, \psi \in T_\Sigma$. Then, by the family regularity of I^b , $I_\Sigma^b[\phi, \psi] \leq T$. Hence, by Proposition 99, we get $I_\Sigma^b[\phi, \psi] \leq \overleftarrow{T}$. Since $\overleftarrow{T} \in \text{ThSys}(\mathcal{I})$, by syntactic prealgebraicity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(\overleftarrow{T})$. Therefore, $\mathcal{I}$ is right regular.

- (b) This part is straightforward, since, by syntactic prealgebraicity, for all $T \in \text{ThSys}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$ if and only if $I_\Sigma^b[\phi, \psi] \leq T$. ■

Propositions 1269 and 1270 may be viewed as partial justifications for the definitions of syntactic regular pre- and proto-algebraicity. Moreover, recalling the following hierarchies of syntactic pre- and protoalgebraicity, of the regularity properties of I^b and of semantic regularity,

the following hierarchy of syntactic classes of regularly pre- and protoalgebraic π -institutions emerges.

We present some examples to show that the hierarchy does not collapse in general. The first is of a π -institution that is syntactically family regularly prealgebraic, but not syntactically system regularly protoalgebraic. It shows that the two southwest arrows in the diagram denote proper inclusions.

Example 1271 EXAMPLE NOT FOUND YET!

The second is of a syntactically system regularly protoalgebraic π -institution which, however, is not syntactically family regularly prealgebraic. So it shows that the two southeast arrows in the diagram denote proper inclusions.

Example 1272 EXAMPLE NOT FOUND YET!

These four classes relate with their immediately subordinate properties on the syntactic side, as shown in the following diagram

and with the four semantic regularity classes, as revealed by Propositions 1269 and 1270, as shown in the following diagram.

Theorem 584, which provided a characterization of both family and of system regularity in terms of the Suszko operator and of a system version of the Suszko operator, respectively, gives rise to the following characterizations of family and system regularity of witnessing collections of natural transformations for the proto- and pre-algebraicity, respectively, of a π -institution.

Corollary 1273 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a collection of natural transformations in N^b , with two distinguished arguments.*

- (a) If $\mathcal{I}$ is syntactically protoalgebraic, with witnessing transformations I^b , then I^b is family regular in $\mathcal{I}$ if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \widetilde{\Omega}_{\Sigma}^{\mathcal{I}}(C(\phi, \psi));$$

- (ba) If $\mathcal{I}$ is syntactically prealgebraic, with witnessing transformations I^b , then I^b is system regular in $\mathcal{I}$ if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \widehat{\Omega}_{\Sigma}^{\mathcal{I}}(\vec{C}(\phi, \psi)).$$

Proof: Part (a) follows by combining Part (a) of Proposition 1269 with the characterization of family regularity given in Theorem 584. Similarly, Part (b) follows by combining Part (b) of Proposition 1270 with the characterization of system regularity given in Theorem 584. ■

The next results form transfer theorems, asserting that all four types of syntactic regularity, studied here, transfer from a π -institution to all its generalized matrix families/systems. We start with the two types obtained by strengthening syntactic protoalgebraicity.

Theorem 1274 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family (system, respectively) regularly protoalgebraic, with witnessing transformations $I^b : (\text{SEN}^b)^{\omega} \rightarrow \text{SEN}^b$, if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ (and all $T' \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, respectively), all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,*

- $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\mathcal{A}}(T)$ iff $I_{\Sigma}^{\mathcal{A}}[\phi, \psi] \leq T$;
- $\phi, \psi \in T_{\Sigma}$ implies $I_{\Sigma}^{\mathcal{A}}[\phi, \psi] \leq T$ ($\phi, \psi \in T'_{\Sigma}$ implies $I_{\Sigma}^{\mathcal{A}}[\phi, \psi] \leq T'$, respectively).

Proof: $\mathcal{I}$ is syntactically regularly protoalgebraic if and only if, by definition, it is syntactically protoalgebraic, with witnessing transformations I^b , which are family regular, if and only if, by Theorem 810 and Proposition 1268, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically protoalgebraic, with witnessing transformations $I^{\mathcal{A}}$, which are family regular in $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$, if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the two conditions asserted in the statement hold.

The case of system regularity may be treated similarly. ■

We close with the two types that only require syntactic prealgebraicity.

Theorem 1275 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family (system, respectively) regularly prealgebraic with witnessing transformations $I^b : (\text{SEN}^b)^{\omega} \rightarrow$*

SEN^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $T' \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,

- $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^A(T')$ iff $I_{\Sigma}^A[\phi, \psi] \leq T'$;
- $\phi, \psi \in T_{\Sigma}$ implies $I_{\Sigma}^A[\phi, \psi] \leq T$ ($\phi, \psi \in T'_{\Sigma}$ implies $I_{\Sigma}^A[\phi, \psi] \leq T'$, respectively).

Proof: Similar to the proof of Theorem 1274. ■

16.4 Syntactic Regular (Pre-)Equivalentiality

Syntactic regular pre- and protoalgebraicity were defined by combining syntactic pre- and protoalgebraicity, respectively, with versions of regularity. If we upgrade syntactic pre- and protoalgebraicity to syntactic preequivalentiality and equivalentiality, respectively, then we obtain, analogously, versions of syntactic regular preequivalentiality and syntactic regular equivalentiality, respectively.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is said to be **syntactically family regularly equivalential** if it is syntactically equivalential, with a witnessing collection I^b of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly equivalential** if it is syntactically equivalential, with a witnessing collection I^b of transformations, which is system regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically family regularly preequivalential** if it is syntactically preequivalential, with a witnessing collection I^b of transformations, which is family regular in $\mathcal{I}$;
- $\mathcal{I}$ is said to be **syntactically system regularly preequivalential** if it is syntactically preequivalential, with a witnessing collection I^b of transformations, which is system regular in $\mathcal{I}$.

Analogues of Propositions 1269 and 1270 may be proven. They follow the same lines of proof, the only difference being that the witnessing collections of transformations we are dealing with in this case, as opposed to the cases of syntactic pre- and protoalgebraicity, are parameter free.

Corollary 1276 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically equivalential π -institution based on $\mathbf{F}$, with witnessing transformations $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$.*

- (a) $\mathcal{I}$ is family regular if and only if $I^\flat$ is family regular in $\mathcal{I}$;
 (b) $\mathcal{I}$ is left regular if and only if $I^\flat$ is system regular in $\mathcal{I}$.

Proof: By Proposition 1269, taking into account the fact that syntactic equivalentiality is equivalent to syntactic protoalgebraicity via a parameter free collection of transformations. ■

Corollary 1277 Let $\mathbf{F} = \langle \mathbf{Sign}^\flat, \mathbf{SEN}^\flat, N^\flat \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically preequivalential π -institution based on $\mathbf{F}$, with witnessing transformations $I^\flat : (\mathbf{SEN}^\flat)^2 \rightarrow \mathbf{SEN}^\flat$.

- (a) $\mathcal{I}$ is right regular if and only if $I^\flat$ is family regular in $\mathcal{I}$;
 (b) $\mathcal{I}$ is system regular if and only if $I^\flat$ is system regular in $\mathcal{I}$.

Proof: By Proposition 1270, taking into account the fact that syntactic preequivalentiality is equivalent to syntactic prealgebraicity via a parameter free collection of transformations. ■

Recalling the following hierarchies of syntactic (pre)equivalentiality, of the regularity properties of $I^\flat$ and of semantic regularity,

the following hierarchy of syntactic classes of regularly (pre)equivalential π -institutions arises.

We present some examples to show that the hierarchy does not collapse in general. The first is of a π -institution that is syntactically family regularly preequivalential, but not syntactically system regularly equivalential. It shows that the two southwest arrows in the diagram denote proper inclusions.

Example 1278 EXAMPLE NOT FOUND YET!

The second is of a syntactically system regularly equivalential π -institution which, however, is not syntactically family regularly preequivalential. So it shows that the two southeast arrows in the diagram denote proper inclusions.

Example 1279 EXAMPLE NOT FOUND YET!

These four classes relate to their immediately subordinate properties on the syntactic side, as shown in the following diagram.

Moreover, from the fact that syntactic equivalentiality is equivalent to syntactic protoalgebraicity, with a parameter free witnessing collection of transformations, and, similarly for preequivalentiality and prealgebraicity, we get, immediately from the definitions the following hierarchy of classes of π -institutions involving syntactic regular pre- and protoalgebraicity and syntactic regular (pre)equivalentiality.

An analog to Corollary 1273 addresses the special case in which the collection I^b witnessing syntactic pre- or protoalgebraicity is parameter free, thus giving rise, instead, to syntactic preequivalentiality or equivalentiality, respectively.

Corollary 1280 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ a collection of natural transformations in N^b (with both arguments distinguished).*

- (a) *If $\mathcal{I}$ is syntactically equivalential, with witnessing transformations I^b , then I^b is family regular in $\mathcal{I}$ if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,*

$$\langle \phi, \psi \rangle \in \widetilde{\Omega}_{\Sigma}^{\mathcal{I}}(C(\phi, \psi));$$

- (b) *If $\mathcal{I}$ is syntactically preequivalential, with witnessing transformations I^b , then I^b is system regular in $\mathcal{I}$ if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,*

$$\langle \phi, \psi \rangle \in \widehat{\Omega}_{\Sigma}^{\mathcal{I}}(\vec{C}(\phi, \psi)).$$

Proof: Each part is a consequence of the corresponding part of Corollary 1273 and the fact that I^b is assumed to be parameter free. $\blacksquare$

Finally, the transfer theorems for syntactic regular pre- and protoalgebraicity, Theorems 1274 and 1275, may also be easily adapted to provide analogous transfer theorems for syntactic regular preequivalentiality and equivalentiality, respectively.

Corollary 1281 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family (system, respectively) regularly equivalential, with witnessing transformations $I^b : (\mathbf{SEN}^b)^2 \rightarrow$*

SEN^b , if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ (and all $T' \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, respectively), all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,

- $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^A(T)$ iff $I_{\Sigma}^A[\phi, \psi] \leq T$;
- $\phi, \psi \in T_{\Sigma}$ implies $I_{\Sigma}^A[\phi, \psi] \leq T$ ($\phi, \psi \in T'_{\Sigma}$ implies $I_{\Sigma}^A[\phi, \psi] \leq T'$, respectively).

Proof: Directly from Theorem 1274. ■

We close with the two versions that only require syntactic preequivalentiality.

Corollary 1282 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family (system, respectively) regularly pre-equivalential with witnessing transformations $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$, if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $T' \in \text{FiSys}^{\mathcal{I}}(\mathcal{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,

- $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^A(T')$ iff $I_{\Sigma}^A[\phi, \psi] \leq T'$;
- $\phi, \psi \in T_{\Sigma}$ implies $I_{\Sigma}^A[\phi, \psi] \leq T$ ($\phi, \psi \in T'_{\Sigma}$ implies $I_{\Sigma}^A[\phi, \psi] \leq T'$, respectively).

Proof: Follows from Theorem 1275. ■

16.5 Syntactic Assertionality

In this section, we study some of the consequences of adding to the various versions of semantic regularity, studied in detail in Section 8.2, the property of having natural theorems.

Recall, first, from Section 8.2, that there are four distinct types of semantic regularity, namely, family, right, left and system, which form the hierarchy depicted in the left diagram (obtained in Section 8.2).

If to the various regularity conditions, one adds the existence of theorems, then one obtains the semantic assertional classes, which were studied in detail in Section 8.3, where it was shown that they form the hierarchy depicted in the diagram on the right.

Additionally, it was shown in Section 8.3 that these three assertional classes dominate, respectively, the three corresponding complete reflectivity classes. This is shown in the third diagram, reproduced here from Section 8.3.

In this section, we study the classes arising by adding to the various flavors of semantic regularity the property of possessing natural theorems. Since the property of possessing natural theorems is strictly stronger than having theorems, there are, in accordance with the results recalled from Section 8.3 above, only three potentially different classes of π -institutions arising. These, of course, dominate the corresponding assertional classes. The π -institution members of these classes are termed *syntactically assertional*. A strong motivation for introducing these three classes lies in the fact that lifting the possession of theorems to that of the existence of natural theorems, in tandem with semantic regularity, is enough to allow passing from the semantic classes of completely reflective π -institutions to the corresponding syntactic classes of truth equational π -institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically family assertional** if it is family regular and has natural theorems;
- $\mathcal{I}$ is **syntactically left assertional** if it is left regular and has natural theorems;
- $\mathcal{I}$ is **syntactically right assertional** if it is right regular and has natural theorems;

- $\mathcal{I}$ is **syntactically system assertional** if it is system regular and has natural theorems.

First, it is easy to see that syntactic family and syntactic right assertional-ity coincide.

Proposition 1283 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family assertional if and only if it is syntactically right assertional.*

Proof: $\mathcal{I}$ is syntactically family assertional iff, by definition, it is family assertional and has natural theorems iff, by Proposition 591, it is right assertional and has natural theorems iff, by definition, it is syntactically right assertional. ■

Given Proposition 1283, asserting that syntactic family and syntactic right assertional-ity coincide, we may establish the hierarchy of syntactic assertional-ity classes.

Proposition 1284 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically family/right assertional, then it is syntactically left assertional;*
- (b) *If $\mathcal{I}$ is syntactically left assertional, then it is syntactically system as-assertional.*

Proof: If $\mathcal{I}$ is syntactically family assertional, then it is, by definition, family assertional and has natural theorems, whence, by Proposition 592, it is left assertional and has natural theorems, i.e., it is syntactically left assertional. Similarly, if $\mathcal{I}$ is syntactically left assertional, then it is, by definition, left assertional and has natural theorems, whence, by Proposition 592, it is system assertional and has natural theorems, i.e., it is syntactically system assertional. ■

Proposition 1284 establishes the following hierarchy of syntactic assertional-ity classes, paralleling the corresponding semantic hierarchy established in Section 8.3.

It is not difficult to see that the bottom classes of the hierarchy collapse, if restricted to stable π -institutions, and that the entire hierarchy collapses when considering only systemic π -institutions.

Proposition 1285 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is stable and syntactically system assertional, then it is syntactically left assertional;*
- (b) *If $\mathcal{I}$ is systemic and syntactically system assertional, then it is syntactically family assertional.*

Proof: The first statement follows directly from Proposition 579, whereas the second implication is a consequence of Proposition 580. ■

We present now examples to show that the hierarchy does not collapse in general. The first is of a π -institution that is syntactically left assertional, but not syntactically family assertional. It shows that the top arrow in the diagram denotes a proper inclusion.

Example 1286 EXAMPLE NOT FOUND YET!

The second is of a syntactically system assertional π -institution which, however, is not syntactically left assertional. So it shows that the bottom arrow in the diagram denotes a proper inclusion.

Example 1287 EXAMPLE NOT FOUND YET!

We formalize, next, a result, which is straightforward, establishing the close interrelationships between the syntactic and semantic assertional classes.

Proposition 1288 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family (respectively left, system) assertional if and only if it is family (respectively left, system) assertional and has natural theorems.*

Proof: These equivalences follow by the definitions involved, since existence of natural theorems implies having theorems, as was shown in Lemma 1203. ■

Thus, Proposition 1288 establishes the following relationships between the semantic assertional and the corresponding syntactic assertional classes.

It is not difficult to show, by providing an example, that the syntactic classes are properly included in the semantic ones. More precisely, we provide an example of a π -institution which is family assertional but fails to be syntactically system assertional. Thus, it belongs to all three semantic assertional classes but in none of the three syntactic assertional steps of the hierarchy.

Example 1289 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be the algebraic system determined as follows:

- $\mathbf{Sign}^b$ is the trivial category with a single object Σ ;
- $\mathbf{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is specified by $\mathbf{SEN}^b(\Sigma) = \{0, 1\}$;
- N^b is the trivial category of natural transformations.

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be the π -institution determined by $\mathcal{C}_\Sigma = \{\{1\}, \{0, 1\}\}$.

$\mathcal{I}$ has two theory families, $\text{Thm}(\mathcal{I})$ and SEN^b , which are also theory systems. Moreover, $\Omega(\text{Thm}(\mathcal{I})) = \Delta^{\mathbf{F}}$ and $\Omega(\text{SEN}^b) = \nabla^{\mathbf{F}}$.

$$\begin{array}{ccc} \text{SEN}^b & \xrightarrow{\quad \quad \quad} & \nabla^{\mathbf{F}} \\ \downarrow & & \downarrow \\ \text{Thm}(\mathcal{I}) & \xrightarrow{\quad \quad \quad} & \Delta^{\mathbf{F}} \end{array}$$

Clearly, $\mathcal{I}$ is family regular, i.e., for all $T \in \text{ThFam}(\mathcal{I})$, and all $x, y \in \{0, 1\}$, if $x, y \in T_\Sigma$, then $\langle x, y \rangle \in \Omega_\Sigma(T)$. Further, obviously, $\mathcal{I}$ has theorems. Finally, since there are no nontrivial natural transformations in N^b , $\mathcal{I}$ does not have natural theorems. Therefore, $\mathcal{I}$ is family assertional but it fails to be syntactically system assertional.

A corollary of the connections established in Proposition 1288 and the characterizations of semantic assertional classes, given in Proposition 588, provides similar characterizations of the three syntactic assertional classes.

Corollary 1290 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution having natural theorems and $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$ a natural theorem.*

- (a) $\mathcal{I}$ is syntactically family assertional if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \tau / \Omega(T)$;
- (b) $\mathcal{I}$ is syntactically left assertional if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \tau / \Omega(T)$;
- (c) $\mathcal{I}$ is syntactically system assertional if and only if, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \tau / \Omega(T)$.

Proof: By combining Propositions 1288 and 588. ■

We conclude the section by establishing the relationships between the three syntactic assertional classes and the three truth equationality classes, introduced and studied in detail in Chapter 11.

Theorem 1291 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically family assertional, with a natural theorem $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$, then it is family truth equational, with witnessing equation $\iota \approx \tau$;*
- (b) *If $\mathcal{I}$ is syntactically left assertional, with a natural theorem $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$, then it is left truth equational, with witnessing equation $\iota \approx \tau$;*

- (c) If $\mathcal{I}$ is syntactically system assertional, with a natural theorem $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$, then it is system truth equational, with witnessing equation $\iota \approx \tau$.

Proof: We prove Part (a). The other parts can be proven similarly. Suppose that $\mathcal{I}$ is syntactically family assertional, with $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$ a natural theorem. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$. To show that $\mathcal{I}$ is family truth equational, with witnessing equation $\iota \approx \tau$, we must establish the equivalence

$$\phi \in T_\Sigma \quad \text{iff} \quad (\iota \approx \tau)_\Sigma[\phi] \leq \Omega(T).$$

Suppose, first, that $\phi \in T_\Sigma$. Since τ is a natural theorem, we also have $\tau_\Sigma(\phi) \in T_\Sigma$. Thus, by family regularity (part of syntactic family assertionality), $\langle \phi, \tau_\Sigma(\phi) \rangle \in \Omega_\Sigma(T)$. But $\Omega(T)$ is a congruence system on $\mathbf{F}$, whence, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\langle \text{SEN}^b(f)(\phi), \tau_{\Sigma'}(\text{SEN}^b(f)(\phi)) \rangle \in \Omega_{\Sigma'}(T),$$

i.e., $(\iota \approx \tau)_\Sigma[\phi] \leq \Omega(T)$.

Assume, conversely, that $(\iota \approx \tau)_\Sigma[\phi] \leq \Omega(T)$. In particular, $\langle \phi, \tau_\Sigma(\phi) \rangle \in \Omega_\Sigma(T)$. However, since τ is a natural theorem, $\tau_\Sigma(\phi) \in T_\Sigma$. Therefore, by the compatibility of $\Omega(T)$ with T , we get that $\phi \in T_\Sigma$. ■

Theorem 1291 establishes the following mixed hierarchy of syntactic assertionality and truth equationality classes.

It is not difficult to see that the syntactic assertionality classes are properly included in the corresponding truth equationality classes. This is accomplished by exhibiting a π -institution which is family truth equational but fails to be syntactically system assertional.

Example 1292 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be the algebraic system defined as follows:

- $\mathbf{Sign}^b$ is the trivial category with object Σ ;

- $\text{SEN}^b : \mathbf{Sign}^b \rightarrow \mathbf{Set}$ is defined by $\text{SEN}^b(\Sigma) = \{0, 1, 2\}$;
- N^b is the clone generated by the unary natural transformations $\sigma^b : \text{SEN}^b \rightarrow \text{SEN}^b$, specified by

$$\sigma_\Sigma^b(0) = 0, \quad \sigma_\Sigma^b(1) = 1, \quad \sigma_\Sigma^b(2) = 0,$$

and $\tau^b : \text{SEN}^b \rightarrow \text{SEN}^b$, given by

$$\tau_\Sigma^b(0) = 2, \quad \tau_\Sigma^b(1) = 1, \quad \tau_\Sigma^b(2) = 2.$$

Define the π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ by stipulating that

$$\mathcal{C}_\Sigma = \{\{1, 2\}, \{0, 1, 2\}\}.$$

$\mathcal{I}$ is systemic and its lattice of theory families and corresponding Leibniz congruence systems are shown in the diagram.

It is not difficult to check that $\mathcal{I}$ is family truth equational, with witnessing equation $\iota \approx \tau^b$.

On the other hand, $\mathcal{I}$ is not system regular, since, for $T = \{\{1, 2\}\}$, we have $1, 2 \in T_\Sigma$, but $\langle 1, 2 \rangle \notin \Delta_\Sigma^F = \Omega_\Sigma(T)$.

Thus, $\mathcal{I}$ belongs to all three truth equationality classes, but does not satisfy any of the three regularity conditions and, hence, belongs to none of the three syntactic assertional classes.

Finally, if we add the corresponding semantic classes of those depicted in the preceding diagram, we get a bigger view of the hierarchy consisting of assertional (semantic and syntactic) and of complete reflectivity (semantic) and truth equationality (syntactic) classes.

In closing, based on previously established results, we can easily show that the three types of syntactic assertional transfer from a π -institution to all its generalized matrix families. This constitutes an analog of Theorem 599 in the syntactic context.

Theorem 1293 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically family (respectively, left, system) assertional if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\langle \mathbf{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically family (respectively, left, system) assertional.*

Proof: This follows by putting together Theorem 585, asserting that regularity transfers, and Theorem 1212, asserting that the existence of natural theorems transfers. ■

16.6 Syntactic RW Prealgebraizability

In this section, we deal with three versions of syntactic regular weak prealgebraizability. These arise by combining syntactic prealgebraicity with each of the three versions of syntactic assertional.

Definition 1294 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically regularly weakly family prealgebraizable**, or **syntactically RWF prealgebraizable** for short, if it is syntactically prealgebraic and syntactically family assertional;
- $\mathcal{I}$ is **syntactically regularly weakly left prealgebraizable**, or **syntactically RWL prealgebraizable** for short, if it is syntactically prealgebraic and syntactically left assertional;
- $\mathcal{I}$ is **syntactically regularly weakly system prealgebraizable**, or **syntactically RWS prealgebraizable** for short, if it is syntactically prealgebraic and syntactically system assertional.

Based on the syntactic assertional hierarchy established in Proposition 1284, we have the following

Proposition 1295 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- If $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable, then it is syntactically regularly weakly left prealgebraizable;
- If $\mathcal{I}$ is syntactically regularly weakly left prealgebraizable, then it is syntactically regularly weakly system prealgebraizable.

Proof: Straightforward by combining Definition 1294 and Proposition 1284.

■

Proposition 1295 establishes the syntactic regular weak prealgebraizability hierarchy depicted in the following diagram.

We present some examples to show that the hierarchy does not collapse in general. The first is of a π -institution that is syntactically regularly weakly left prealgebraizable, but not syntactically regularly weakly family prealgebraizable. It shows that the top arrow in the diagram denotes a proper inclusion.

Example 1296 EXAMPLE NOT FOUND YET!

The second is of a syntactically regularly weakly system prealgebraizable π -institution which, however, is not syntactically regularly weakly left prealgebraizable. So it shows that the bottom arrow in the diagram denotes a proper inclusion.

Example 1297 EXAMPLE NOT FOUND YET!

Being very close to the apex of the Leibniz hierarchy, just below the other classes that are studied in detail in the remaining sections of the present chapter, it compares favorably (meaning is stronger) to many of the other classes, semantic and syntactic introduced so far.

First, we look at the extant relationships between syntactic regular weak prealgebraizability classes and the four syntactic regular prealgebraicity classes of Section 16.3. It turns out that syntactic regular weak family prealgebraizability implies syntactic family regular protoalgebraicity and that syntactically regular weak system prealgebraizability implies syntactic system regular prealgebraicity. The only implication one can draw from the middle class of syntactically regular weak left prealgebraizability is the trivial one of being syntactically prealgebraic and left regular, which, strictly speaking, lies outside the syntactic hierarchy of Section 16.3.

Proposition 1298 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically RWF prealgebraizable, then it is syntactically family regularly protoalgebraic;*
- (b) *If $\mathcal{I}$ is syntactically RWS prealgebraizable, then it is syntactically system regularly prealgebraic.*

Proof:

- (a) Suppose that $\mathcal{I}$ is syntactically RWF prealgebraizable. Note that, by definition, $\mathcal{I}$ is syntactically family assertional, i.e., it is family regular and has natural theorems. Thus, by Theorem 1291, it is family truth equational. So, by Theorem 830, it is family c-reflective, whence, by Proposition 237, it is systemic. Thus, since, by definition, it is syntactically prealgebraic, it must be syntactically protoalgebraic. This proves that it is syntactically family regularly protoalgebraic.
- (b) By definition $\mathcal{I}$ is syntactically system assertional, whence it is system regular. And it is syntactically prealgebraic, also by definition. Thus, it is syntactically system regularly prealgebraic.

■

Thus, according to Proposition 1298, we get the mixed hierarchy depicted in the diagram.

We give an example that separates the two hierarchies, i.e., shows that all three southwest arrows denote proper inclusions. It presents a syntactically family regularly protoalgebraic π -institution which fails to be syntactically regularly weakly system prealgebraizable.

Example 1299 EXAMPLE NOT FOUND YET!

As far as relationships between the syntactic regular weak prealgebraizability hierarchy and the syntactic assertability hierarchy are concerned, we have, directly by definition, the following inclusions.

Proposition 1300 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically regularly weakly family (left, system, respectively) prealgebraizable, then it is syntactically family (left, system, respectively) assertional.*

Proof: Directly from Definition 1294. ■

We give an example that separates the two hierarchies, i.e., shows that all three southeast arrows denote proper inclusions. It presents a syntactically family assertional π -institution which fails to be syntactically regularly weakly system prealgebraizable.

Example 1301 EXAMPLE NOT FOUND YET!

Finally we look at closer relationships with other classes that are placed relatively high in the Leibniz hierarchy. Still staying with syntactically defined classes, we have the following relationships between the classes in the syntactic regular weak prealgebraizability hierarchy and the classes in the syntactic weak prealgebraizability hierarchy, which were defined in Chapter 12.

Proposition 1302 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable, then it is syntactically weakly family algebraizable;*
- (b) *If $\mathcal{I}$ is syntactically regularly weakly left prealgebraizable, then it is syntactically weakly left c -reflective prealgebraizable;*
- (c) *If $\mathcal{I}$ is syntactically regularly weakly system prealgebraizable, then it is syntactically weakly system prealgebraizable.*

Proof: We only prove Part (a). Parts (b) and (c) can be proven similarly and are easier. Suppose $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable. Then, it is, by definition syntactically family assertional. Thus, by Theorem 1291, it is family truth equational and, therefore, systemic. Thus, on the one hand, $\mathcal{I}$ is syntactically prealgebraic, and, hence, by systemicity, syntactically protoalgebraic, and, on the other, it is family truth equational. Therefore, it is syntactically weakly family algebraizable. ■

Proposition 1302, establishes the following hierarchy of syntactically regularly weakly prealgebraizable and syntactically weakly prealgebraizable π -institutions.

This hierarchy can also be separated. We present an example of a π -institution which is syntactically weakly family algebraizable but fails to be syntactically regularly weakly system prealgebraizable and, therefore, shows that all southwest arrows in the diagram denote proper inclusions.

Example 1303 EXAMPLE NOT FOUND YET!

Finally, we reach across to bridge the gap between syntactically and semantically defined prealgebraizability classes. We establish relationships that govern the syntactic regular weak prealgebraizability classes and the regular weak prealgebraizability classes that were defined in Chapter 8.

Proposition 1304 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable, then it is regularly weakly family algebraizable;*
- (b) *If $\mathcal{I}$ is syntactically regularly weakly left prealgebraizable, then it is regularly weakly left prealgebraizable;*
- (c) *If $\mathcal{I}$ is syntactically regularly weakly system prealgebraizable, then it is regularly weakly system prealgebraizable.*

Proof: This follows from the facts that, on the one hand, syntactic prealgebraicity implies prealgebraicity and, on the other hand, syntactic family (left, system, respectively) assertionality implies family (left, system, respectively) assertionality. ■

Proposition 1304 gives rise to the following mixed, semantic and syntactic, hierarchy of regularly weakly prealgebraizable π -institutions.

Based on existing results, we can show that all three kinds of syntactic regular weak prealgebraizability transfer from theory families/systems to filter families/systems over arbitrary $\mathbf{F}$ -algebraic systems. This is the syntactic analog of Theorem 609, which asserted that regular weak prealgebraizability properties transfer from a π -institution to all its generalized matrix families.

Theorem 1305 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically regularly weakly family (left, system, respectively) prealgebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the $\mathcal{I}$ -gmatrix family $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically regularly weakly family (left, system, respectively) prealgebraizable.*

Proof: By Theorem 789, syntactic prealgebraicity transfers. By Theorem 585, the three regularity properties transfer. Finally, by Theorem 1212, the property of possessing natural theorems also transfers. Thus, the properties of being syntactically regularly weakly family, left and system prealgebraizable all transfer from $\mathcal{I}$ to $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}$. ■

Finally, we adapt previously obtained results characterizing regular weak prealgebraizability to obtain similar characterizations of syntactic regular weak prealgebraizability in terms of mappings between posets of filter families/systems (including theory families/systems) and congruence systems. Essentially, to the characterizations obtained in Theorems 610, 611 and 612, we add the conditions of having enough natural transformations so that syntactic prealgebraicity is ensured and also the existence of natural theorems so that truth equationality is obtained, rather than having only complete reflectivity.

Theorem 1306 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable;

- (ii) $\Omega : \text{ThFam}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is an order isomorphism, $\mathcal{I}$ has a Leibniz reflexive core and a natural theorem $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$, such that, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Proof: By Theorem 1336, $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is also syntactically regularly weakly family prealgebraizable. Thus, to prove the statement, it suffices to consider the equivalence (i) $\Leftrightarrow$ (ii).

Suppose, first, that $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable. Then it is, by definition, syntactically prealgebraic. Moreover, it is, by definition, syntactically family assertional. Thus, it has a natural theorem τ and it is, by Theorem 1291, family truth equational. Thus, by Theorem 830, it is family c-reflective and, hence, by Proposition 237, systemic. This implies that it is syntactically protoalgebraic and family truth equational. Using Theorem 610, we conclude that Ω is an order isomorphism. By Theorem 788, it has a Leibniz reflexive core and, by Corollary 1290, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$.

Assume, conversely, that the postulated conditions hold. By Proposition 1304, $\mathcal{I}$ is regularly weakly family prealgebraizable. Hence it is protoalgebraic, which, together with the postulated Leibniz property of the reflexive core, gives, by Corollary 809, that it is syntactically protoalgebraic. Further, by hypothesis and Corollary 1290, it is syntactically family assertional. Thus, by definition, it is syntactically regularly weakly family prealgebraizable. ■

Analogous characterization theorems may be provided for syntactical regular weak left and system prealgebraizability. The proofs are similar and are omitted.

Theorem 1307 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:

- (i) $\mathcal{I}$ is syntactically regularly weakly left prealgebraizable;
- (ii) $\Omega : \text{ThSys}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is an order embedding, $\mathcal{I}$ has a Leibniz reflexive core and a natural theorem $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$, such that, for all $T \in \text{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Theorem 1308 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:

- (i) $\mathcal{I}$ is syntactically regularly weakly system prealgebraizable;

- (ii) $\Omega : \text{ThSys}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is an order embedding, $\mathcal{I}$ has a Leibniz reflexive core and a natural theorem $\tau : \text{SEN}^b \rightarrow \text{SEN}^b$, such that, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

16.7 Syntactic RW Algebraizability

In this section, we deal with three versions of syntactic regular weak algebraizability. These arise by combining syntactic protoalgebraicity with each of the three versions of syntactic assertionality.

Definition 1309 Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically regularly weakly family algebraizable**, or **syntactically RWF algebraizable** for short, if it is syntactically protoalgebraic and syntactically family assertional;
- $\mathcal{I}$ is **syntactically regularly weakly left algebraizable**, or **syntactically RWL algebraizable** for short, if it is syntactically protoalgebraic and syntactically left assertional;
- $\mathcal{I}$ is **syntactically regularly weakly system algebraizable**, or **syntactically RWS algebraizable** for short, if it is syntactically protoalgebraic and syntactically system assertional.

One of the immediate consequences of family assertionality is that the π -institution under consideration must be systemic and, therefore, that pre- and protoalgebraicity coincide. This reasoning has been applied a few times already in the preceding section. It shows that syntactic regular weak family algebraizability coincides with syntactic weak family prealgebraizability.

Proposition 1310 Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically regularly weakly family algebraizable if and only if it is syntactically regularly weakly family prealgebraizable.

Proof: Suppose $\mathcal{I}$ is syntactically regularly weakly family prealgebraizable. Then, by definition, it is family assertional. Thus, by Theorem 1291, it is family truth equational. Hence, by Theorem 830, it is family completely reflective and, therefore, by Proposition 237, it is systemic. Since, by definition, it is syntactically prealgebraic, it is, by systemicity, syntactically protoalgebraic. Being syntactically protoalgebraic and syntactically family assertional, it is

syntactically regularly weakly family algebraizable. The reverse implication is trivial. So, equivalence of the two conditions is established. ■

The second important observation that one can make is that syntactic regular weak left and system algebraizability coincide. This is due to the fact that protoalgebraicity implies stability.

Proposition 1311 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically regularly weakly left algebraizable if and only if it is syntactically regularly weakly system algebraizable.*

Proof: It is easy to see that the left version implies the system version. This follows directly from the fact that syntactic left assertional implies syntactic system assertional, established in Proposition 1284. For the converse, assume that $\mathcal{I}$ is syntactically regularly weakly system algebraizable. Then it is, by definition, syntactically protoalgebraic. This implies, by Theorem 805, that it is protoalgebraic. Hence, by Theorem 175, it is stable. Now, also by definition, $\mathcal{I}$ is syntactically system assertional. Thus, by Proposition 1285, it is syntactically left assertional. Being syntactically protoalgebraic and syntactically left assertional, $\mathcal{I}$ is, by definition, syntactically regularly weakly left algebraizable. ■

Based on the syntactic assertional hierarchy established in Proposition 1284, we have the following

Corollary 1312 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically regularly weakly family algebraizable, then it is syntactically regularly weakly system algebraizable.*

Proof: Straightforward by combining Definition 1309 and Proposition 1284. ■

Proposition 1312 establishes the syntactic regular weak algebraizability hierarchy depicted in the following diagram.

It is easy to see how the two classes introduced in this section fit within a mixed syntactic regular weak (pre)algebraizability hierarchy. Given Proposition 1310, which showed that the top classes in each of the two hierarchies coincide, the picture is completed by the following easy consequence of the definitions involved.

Proposition 1313 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically regularly weakly system algebraizable, then it is syntactically regularly weakly left prealgebraizable.*

Proof: If $\mathcal{I}$ is syntactically regularly weakly system algebraizable, then, by Proposition 1311, it is syntactically regularly weakly left algebraizable, whence, since syntactic protoalgebraicity implies syntactic prealgebraicity, we conclude that $\mathcal{I}$ is syntactically regularly weakly left algebraizable. ■

Thus, the following diagram presents the complete picture consisting of the four syntactic regular weak (pre)algebraizability classes of π -institutions. Compare this with the identical hierarchy revealed on the semantic side in Section 8.5.

Recall that in Examples 1296 and 1297, we separated the top class from the third class and the third class from the bottom class. So, we need a couple of examples that separate the second class, inserted in the hierarchy in this section, from its predecessor and its successor. The following example is of a π -institution that is syntactically regularly weakly system algebraizable, but not syntactically regularly weakly family algebraizable.

Example 1314 EXAMPLE NOT FOUND YET!

The next example is of a syntactically regularly weakly left prealgebraizable π -institution that fails to be syntactically regularly weakly system algebraizable.

Example 1315 EXAMPLE NOT FOUND YET!

To complete the puzzle of the relationships between syntactic regular weak prealgebraizability and syntactic regular pre- and protoalgebraicity classes, it suffices to observe that syntactic regular weak system algebraizability implies, rather trivially, syntactic system regular protoalgebraicity.

Proposition 1316 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically RWS algebraizable, then it is syntactically system regularly protoalgebraic.*

Proof: Suppose that $\mathcal{I}$ is syntactically RWS algebraizable. Note that, by definition, $\mathcal{I}$ is syntactically system assertional, and syntactically protoalgebraic. Hence, it is syntactically system regularly protoalgebraic. ■

Thus, according to both Proposition 1298 and Proposition 1316, we get the following hierarchy, which completes the diagram given in the preceding section after Proposition 1298.

In Example 1299, we constructed a π -institution which is syntactically family regularly protoalgebraic, but not syntactically regularly weakly system prealgebraizable. The example serves to demonstrate that all four southwest arrows in the diagram denote proper inclusions.

As far as relationships between the syntactic regular weak prealgebraizability hierarchy and the syntactic assertional hierarchy are concerned, the picture is completed by realizing that syntactic regular weak system algebraizability implies syntactic left assertional.

Corollary 1317 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically RWS algebraizable, then it is syntactically left assertional.*

Proof: The conclusion follows directly by Proposition 1311. ■

Thus, according to Corollary 1317, and the hierarchy obtained in the preceding section, the interactions with syntactic assertional properties are as shown in the diagram.

In Example 1301, we constructed a π -institution which is syntactically family assertional, but not syntactically regularly weakly system prealgebraizable. The example serves to demonstrate that all three southeast arrows in the diagram denote proper inclusions.

Finally we look at completing the hierarchy diagrams examining the relationships with other classes that are placed relatively high in the Leibniz hierarchy. Staying with syntactically defined classes, we have the following extra relationship between syntactically regularly weakly system algebraizable π -institutions and syntactically weakly (system) algebraizable ones.

Proposition 1318 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically regularly weakly system algebraizable, then it is syntactically weakly (system) algebraizable.*

Proof: Suppose $\mathcal{I}$ is syntactically regularly weakly system algebraizable. Then, it is, by definition syntactically protoalgebraic and system assertional. Thus, by Theorem 1291, it is syntactically protoalgebraic and system truth equational. Therefore, it is, by definition, syntactically weakly (system) algebraizable. ■

Proposition 1318, in conjunction with Proposition 1302, completes the hierarchy of syntactically regularly weakly (pre)algebraizable and syntactically weakly (pre)algebraizable π -institutions, part of which was shown following Proposition 1302.

In Example 1303, we constructed a π -institution which is syntactically weakly family algebraizable, but not syntactically regularly weakly system prealgebraizable. The example serves to demonstrate that all four southwest arrows in the diagram denote proper inclusions.

We revisit, next, the relationships between syntactically and semantically defined (pre)algebraizability classes. We show that syntactic regular weak system algebraizability implies regular weak system algebraizability. This completes the picture established in Proposition 1304.

Proposition 1319 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically regularly weakly system algebraizable, then it is regularly weakly system algebraizable.*

Proof: This follows from the facts that, on the one hand, by Theorem 805, syntactic protoalgebraicity implies protoalgebraicity and, on the other hand, by Proposition 1288, syntactic system assertionalty implies system assertionalty. ■

Propositions 1304 and 1319 give rise to the following mixed, semantic and syntactic, hierarchy of regularly weakly (pre)algebraizable π -institutions, which completes the hierarchy shown after Proposition 1304.

As was the case with the three syntactic regular weak prealgebraizability classes, we may show that syntactic regular weak system algebraizability also transfers from theory families/systems to filter families/systems over arbitrary $\mathbf{F}$ -algebraic systems. This completes Transfer Theorem 1305.

Theorem 1320 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is syntactically regularly weakly system algebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically regularly weakly system algebraizable.*

Proof: By Theorem 810, syntactic protoalgebraicity transfers. By Theorem 585, system regularity transfers. Finally, by Theorem 1212, the property of possessing natural theorems also transfers. Thus, syntactic regular weak system algebraizability transfers from $\mathcal{I}$ to $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}$. This establishes the theorem. ■

Finally, we adapt previously obtained results characterizing syntactic regular weak prealgebraizability to obtain a similar characterization of syntactic regular weak system algebraizability in terms of mappings between posets of filter families/systems (including theory families/systems) and congruence systems. This completes Theorem 1306.

Theorem 1321 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is syntactically regularly weakly system algebraizable;
- (ii) $\mathcal{I}$ is stable, $\Omega : \mathbf{ThSys}(\mathcal{I}) \rightarrow \mathbf{ConSys}^*(\mathcal{I})$ is an order isomorphism, $\mathcal{I}$ has a Leibniz reflexive core and a natural theorem $\tau : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$, such that, for all $T \in \mathbf{ThSys}(\mathcal{I})$, $T = \tau/\Omega(T)$;

- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Proof: By Theorem 1320, $\mathcal{I}$ is syntactically regularly weakly system algebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is also syntactically regularly weakly system algebraizable. Thus, to prove the statement, it suffices to consider the equivalence (i) $\Leftrightarrow$ (ii).

Suppose, first, that $\mathcal{I}$ is syntactically regularly weakly system algebraizable. Then, it is, in particular, by Proposition 1319, regularly weakly system algebraizable, and, by definition, syntactically protoalgebraic and syntactically system assertional. By Theorem 624, $\mathcal{I}$ is stable, $\Omega : \text{ThSys}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is an order isomorphism and, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \tau / \Omega(T)$, where τ is a natural theorem, whose existence is guaranteed by syntactic assertionality. Finally, syntactic protoalgebraicity implies, by Theorem 805, that $\mathcal{I}$ has a Leibniz reflexive core.

Assume, conversely, that the postulated conditions hold. By Theorem 624, $\mathcal{I}$ is regularly weakly system algebraizable. Hence it is protoalgebraic, which, together with the postulated Leibniz property of the reflexive core, gives, by Theorem 805, that it is syntactically protoalgebraic. Further, since it is regularly weakly system algebraizable, it is, in particular, system regular and, by hypothesis, has natural theorems. Thus, it is syntactically system assertional. Hence, being syntactically protoalgebraic and syntactically system assertional, it is, by definition, syntactically regularly weakly system algebraizable. ■

16.8 Syntactic Regular (Pre)Algebraizability

In this section, we deal with the four versions of syntactic regular (pre)algebraizability, corresponding to the four versions of syntactic regular weak (pre)algebraizability that were studied in the preceding two sections. These arise by combining syntactic (pre)equivalentiality with each of the three versions of syntactic assertionality. They give rise to a four-element linear hierarchy that parallels that of syntactically regularly weakly (pre)algebraizable π -institutions and lies directly above it. The four classes, introduced and studied in the present section, lie at the very apex of the Leibniz hierarchy that was studied in detail in the monograph, and which forms the backbone of the field of categorical abstract algebraic logic.

A priori, one may define six different classes of syntactically regularly (pre)algebraizable π -institutions. Three of these classes use syntactic pre-equivalentiality.

Definition 1322 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically regularly family prealgebraizable**, or **syntactically RF prealgebraizable for short**, if it is syntactically pre-equivalential and syntactically family assertional;
- $\mathcal{I}$ is **syntactically regularly left prealgebraizable**, or **syntactically RL prealgebraizable for short**, if it is syntactically pre-equivalential and syntactically left assertional;
- $\mathcal{I}$ is **syntactically regularly system prealgebraizable**, or **syntactically RS prealgebraizable for short**, if it is syntactically pre-equivalential and syntactically system assertional.

Three more classes use syntactic equivalentiality.

Definition 1323 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **syntactically regularly family algebraizable**, or **syntactically RF algebraizable for short**, if it is syntactically equivalential and syntactically family assertional;
- $\mathcal{I}$ is **syntactically regularly left algebraizable**, or **syntactically RL algebraizable for short**, if it is syntactically equivalential and syntactically left assertional;
- $\mathcal{I}$ is **syntactically regularly system algebraizable**, or **syntactically RS algebraizable for short**, if it is syntactically equivalential and syntactically system assertional.

We can show that similar relationships to those holding between the syntactic regular weak (pre)algebraizability classes are valid in this case also, leading to the collapsing of the six-class hierarchy (which, a priori, would look as in the accompanying figure)

to only four classes forming a linear hierarchy.

The top classes of syntactically regularly family prealgebraizable and algebraizable π -institutions coincide. Moreover, in the algebraizability case, syntactic regular left algebraizability turns out to be identical with syntactic regular system algebraizability. These relationships are presented formally in the following proposition.

Proposition 1324 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically regularly family prealgebraizable if and only if it is syntactically regularly family algebraizable;*
- (b) *$\mathcal{I}$ is syntactically regularly left algebraizable if and only if it is syntactically regularly system algebraizable.*

Proof:

- (a) Of course the right-to-left implication is trivial, since, by definition (see Section 13.3 and 13.4), syntactic equivalentiality implies syntactic preequivalentiality. On the other hand, by Theorem 1291, syntactic family assertionality implies family truth equationality, which, in turn, implies, by Theorem 830, family c-reflectivity and, hence, by Lemma 233, systemicity. Thus, under the given hypothesis, syntactic preequivalentiality coincides with syntactic equivalentiality.
- (b) Again, since it is obvious that syntactic regular left algebraizability implies syntactic system algebraizability, in view of the fact (Proposition 1284) that syntactic left assertionality implies syntactic system assertionality, one must focus on the reverse implication. However, syntactic system algebraizability entails syntactic protoalgebraicity, which implies, by Theorem 792, protoalgebraicity, which, in turn, by Lemma 170, implies stability. And under stability, by Proposition 1285, syntactic left assertionality and syntactic system assertionality coincide. ■

Now the following implications are straightforward and establish the hierarchy obtained from the preceding diagram, if one takes into account the pairwise identification of classes proven in Proposition 1324.

Proposition 1325 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically regularly family (pre)algebraizable, then it is syntactically regularly system (left) algebraizable;*
- (b) *If $\mathcal{I}$ is syntactically regularly system (left) algebraizable, then it is syntactically regularly left prealgebraizable;*

(c) *If $\mathcal{I}$ is syntactically regularly left prealgebraizable, then it is syntactically regularly system prealgebraizable.*

Proof: Part (a) relies on the fact that, by Proposition 1284, syntactic family assertionalty is stronger than syntactic system assertionalty. Part (b) relies on the fact that syntactic equivalentiality implies syntactic preequivalentiality. Finally, Part (c) is a direct consequence of syntactic system assertionalty being dominated by syntactic left assertionalty (Proposition 1284). ■

Proposition 1325, which takes into account the identifications of Proposition 1324, establishes the syntactic regular (pre)algebraizability hierarchy depicted in the following diagram.

We now present three examples to show that all four classes in this hierarchy are different. First, we construct a π -institution that is syntactically regularly system algebraizable, but is not syntactically regularly family algebraizable.

Example 1326 EXAMPLE NOT FOUND YET!

The second example is of a π -institution which is syntactically regularly left prealgebraizable but fails to be syntactically regularly system algebraizable.

Example 1327 EXAMPLE NOT FOUND YET!

The last example in this sequence involves a syntactically regularly system prealgebraizable π -institution which is not syntactically regularly left prealgebraizable.

Example 1328 EXAMPLE NOT FOUND YET!

We look, next, at the relationships between syntactic regular (pre)algebraizability classes and the four syntactic regular (pre)equivalentiality classes of Section 16.4. Syntactic regular family algebraizability implies syntactic family regular equivalentiality, syntactic regular system algebraizability implies syntactic system regular equivalentiality and syntactic regular system prealgebraizability implies syntactic system regular preequivalentiality. However, from syntactic regular left prealgebraizability we can only make the trivial deduction of syntactic preequivalentiality and left regularity. Strictly speaking, the combination of these two properties does not form a class in the syntactic hierarchy of Section 16.4.

Proposition 1329 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically RF algebraizable, then it is syntactically family regularly equivalential;*
- (b) *If $\mathcal{I}$ is syntactically RS algebraizable, then it is syntactically system regularly equivalential;*
- (c) *If $\mathcal{I}$ is syntactically RS prealgebraizable, then it is syntactically system regularly preequivalential.*

Proof: For Part (a) observe that, by definition, $\mathcal{I}$ is syntactically equivalential and syntactically family assertional, which implies that it is family regular. Thus, it is syntactically family regularly equivalential. Similarly, for Part (b), $\mathcal{I}$ is, by definition, syntactically equivalential and syntactically system assertional, which implies system regularity. Thus, it is syntactically system regularly equivalential. Finally, in Part (c), $\mathcal{I}$ is, by definition, syntactically preequivalential and syntactically system assertional, whence, once more, it is also syntactically system regular. Hence, it is syntactically system regularly preequivalential. ■

Thus, according to Proposition 1329, we get the mixed hierarchy depicted in the diagram.

We give an example of a syntactically family regularly equivalential π -institution which fails to be syntactically regularly system prealgebraizable. This demonstrates that all four southwest arrows in the diagram denote proper inclusions.

Example 1330 EXAMPLE NOT FOUND YET!

We do not dwell on relationships between the syntactic regular (pre)algebraizability classes and the syntactic assertionlity classes, since those are direct consequences of the relationships, already established in the preceding section, between syntactic regular weak (pre)algebraizability classes and the syntactic assertionality classes, once the following, also easily obtainable, relations between syntactic regular (pre)algebraizability classes and syntactic regular weak (pre)algebraizability classes are established.

Proposition 1331 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable, then it is syntactically regularly weakly family (system, respectively) algebraizable;*
- (b) *If $\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable, then it is syntactically regularly weakly left (system, respectively) prealgebraizable.*

Proof: Directly from the definitions involved. ■

Thus, we get a comprehensive picture of the syntactic regular prealgebraizability hierarchy, including both weak and “strong” (meaning non-weak) classes.

We give an example of a π -institution which is syntactically regularly weakly family algebraizable but fails to be syntactically regularly system prealgebraizable. This shows that all four southwest arrows in the diagram denote proper inclusions.

Example 1332 EXAMPLE NOT FOUND YET!

Finally we look at the relationships with other classes that are placed just below syntactically regularly (pre)algebraizable π -institutions, namely, the classes in the syntactic (pre)algebraizability hierarchy and those in the (semantic) regular (pre)algebraizability hierarchy. The former hierarchy was studied in detail in Chapter 12, whereas the latter was studied in Chapter 8. Starting with the relationships between the syntactic regular (pre)algebraizability and the syntactic (pre)algebraizability classes, we get the following

Proposition 1333 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable, then it is syntactically family (system, respectively) algebraizable;*
- (b) *If $\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable, then it is syntactically left (system, respectively) prealgebraizable.*

Proof: Part (a) follows from the fact that syntactic family and system assertionalities imply, respectively, family and system truth equationality. Part (b), similarly, follows from the fact that syntactic left and system assertionalities imply, respectively, left and system truth equationality. All the aforementioned implications, forming the key to the inclusions in the statement, are the subject of Theorem 1291. ■

Proposition 1333, establishes the following mixed hierarchy of syntactically regularly (pre)algebraizable and syntactically (pre)algebraizable π -institutions.

We devise an example of a syntactically family algebraizable π -institution that fails to be syntactically regularly system prealgebraizable. This shows that all four southwest arrows in the diagram denote proper inclusions.

Example 1334 EXAMPLE NOT FOUND YET!

We close with the relationships between syntactically and semantically defined regular (pre)algebraizability classes.

Proposition 1335 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable, then it is regularly family (system, respectively) algebraizable;*
- (b) *If $\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable, then it is regularly left (system, respectively) prealgebraizable.*

Proof: This follows from the facts that, on the one hand, syntactic pre- and protoalgebraicity imply respectively pre- and protoalgebraicity, and, on the other hand, syntactic family (left, system, respectively) assertionality implies family (left, system, respectively) assertionality. The former implications are established in Theorems 771 and 792. The latter are by Proposition 1288.

■

Proposition 1335 gives rise to the following mixed, semantic and syntactic, hierarchy of regularly (pre)algebraizable π -institutions.

As was the case with syntactic regular weak (pre)algebraizability, all four flavors of syntactic regular (pre)algebraizability transfer from theory families/systems to filter families/systems over arbitrary $\mathbf{F}$ -algebraic systems. This is a “strong” analog of Theorems 1305 and 1320, which asserted that syntactic regular weak (pre)algebraizability properties transfer from a π -institution to all models of the form $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Theorem 1336 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *$\mathcal{I}$ is syntactically regularly family (system, respectively) algebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically regularly family (system, respectively) algebraizable;*
- (b) *$\mathcal{I}$ is syntactically regularly left (system, respectively) prealgebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is syntactically regularly left (system, respectively) prealgebraizable.*

Proof: By Theorems 960 and 978, syntactic preequivalentiality and syntactic equivalentiality transfer. By Theorem 585, the three regularity properties transfer. Finally, by Theorem 1212, the property of possessing natural theorems also transfers. Thus, all four syntactic regular (pre)algebraizability properties transfer from $\mathcal{I}$ to $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}$. ■

Finally, we obtain characterizations of syntactically regular (pre)algebraizability in terms of mappings between posets of filter families/ systems (including theory families/systems) and congruence systems.

Theorem 1337 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is syntactically regularly family algebraizable;
- (ii) $\Omega : \text{ThFam}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is an order isomorphism commuting with inverse logical extensions, $\mathcal{I}$ has a Leibniz binary reflexive core and a natural theorem $\tau : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$, such that, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Proof: By Theorem 1336, $\mathcal{I}$ is syntactically regularly family algebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ is also syntactically regularly family algebraizable. Thus, to prove the statement, it suffices to consider the equivalence (i) $\Leftrightarrow$ (ii).

Suppose, first, that $\mathcal{I}$ is syntactically regularly family algebraizable. Then it is, by definition, syntactically equivalential and syntactically family assertional. Thus, it has a natural theorem τ , it is family regular and it is, by Theorem 1291, family truth equational. Using Corollary 649, we conclude that Ω is an order isomorphism commuting with inverse logical extensions, by Theorem 989, that it has a Leibniz binary reflexive core and, by Corollary 1290, that, for all $T \in \text{ThFam}(\mathcal{I})$, $T = \tau/\Omega(T)$.

Assume, conversely, that the postulated conditions hold. By Corollary 649, $\mathcal{I}$ is regularly family algebraizable. Hence it is equivalential, whence, together with the postulated Leibniz property of the binary reflexive core, we obtain, by Corollary 989, that it is syntactically equivalential. Further, by hypothesis and Corollary 1290, it is syntactically family assertional. Thus, by definition, it is syntactically regularly family algebraizable. ■

Theorem 1338 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is syntactically regularly system algebraizable;
- (ii) $\mathcal{I}$ is stable, $\Omega : \text{ThSys}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is an order isomorphism commuting with inverse logical extensions, $\mathcal{I}$ has a Leibniz binary reflexive core and a natural theorem $\tau : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$, such that, for all $T \in \text{ThSys}(\mathcal{I})$, $T = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$.

Proof: Similar to that of Theorem 1337. ■

Analogous characterization theorems may be provided for the syntactic regular prealgebraizability properties. The proofs are also similar and are, therefore, omitted.

Theorem 1339 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is syntactically regularly left prealgebraizable;
- (ii) $\Omega : \mathbf{ThSys}(\mathcal{I}) \rightarrow \mathbf{ConSys}^*(\mathcal{I})$ is an order embedding commuting with inverse logical extensions, $\mathcal{I}$ has a Leibniz binary reflexive core and a natural theorem $\tau : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$, such that, for all $T \in \mathbf{ThFam}(\mathcal{I})$, $\overleftarrow{T} = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}.C^{\mathcal{I}, \mathcal{A}} \rangle$.

Theorem 1340 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is syntactically regularly system prealgebraizable;
- (ii) $\Omega : \mathbf{ThSys}(\mathcal{I}) \rightarrow \mathbf{ConSys}^*(\mathcal{I})$ is an order embedding commuting with inverse logical extensions, $\mathcal{I}$ has a Leibniz binary reflexive core and a natural theorem $\tau : \mathbf{SEN}^b \rightarrow \mathbf{SEN}^b$, such that, for all $T \in \mathbf{ThSys}(\mathcal{I})$, $T = \tau/\Omega(T)$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the clauses of Part (ii) hold for the π -institution $\langle \mathcal{A}.C^{\mathcal{I}, \mathcal{A}} \rangle$.

Chapter 17

The Syntactic Leibniz Hierarchy: Attic II

17.1 Introduction

This chapter deals with the issue of finitariness for syntactically defined classes in the hierarchy. An analogous study from the semantic point of view was carried out in Chapter 9.

In Section 17.2, we revisit the finitary companion $\mathcal{I}^f$ of a π -institution $\mathcal{I}$, this time in relation to classes near the top of the syntactic hierarchy. Our goal is to discover conditions under which syntactic properties are inherited by $\mathcal{I}$ from $\mathcal{I}^f$ and vice versa. Recall that the finitary companion $\mathcal{I}^f$ of $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is the π -institution $\mathcal{I}^f = \langle \mathbf{F}, C^f \rangle$, where, for all signatures Σ and all subsets Φ of Σ -sentences,

$$C_\Sigma^f(\Phi) = \bigcup \{C_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\},$$

$\subseteq_f$ denoting the finite subset relation. $\mathcal{I}^f$ is the largest finitary π -institution lying below $\mathcal{I}$ in the $\leq$ ordering. This implies that $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$. Due to this inclusion, many of the key properties related to the algebraic hierarchy that $\mathcal{I}^f$ possesses are inherited by $\mathcal{I}$. E.g., we show that, if $\mathcal{I}^f$ happens to be syntactically protoalgebraic, then so is $\mathcal{I}$. Similarly, if $\mathcal{I}^f$ happens to be truth equational, then so is $\mathcal{I}$. Moreover, under protoalgebraicity of $\mathcal{I}^f$, the Leibniz property is inherited from the reflexive core $R^{\mathcal{I}^f}$ of $\mathcal{I}^f$ by the reflexive core $R^{\mathcal{I}}$ of $\mathcal{I}$. Analogously, under c-reflectivity of $\mathcal{I}^f$, adequacy of the Suszko core $S^{\mathcal{I}^f}$ of $\mathcal{I}^f$ implies adequacy of the Suszko core $S^{\mathcal{I}}$ of $\mathcal{I}$. These properties enable us to show that, if $\mathcal{I}^f$ is syntactically weakly family algebraizable, then so is $\mathcal{I}$.

In the second part of Section 17.2, we turn to some properties that transfer from $\mathcal{I}$ to $\mathcal{I}^f$ rather than in the opposite direction. In Chapter 9 it was shown that continuity of the Leibniz operator implies protoalgebraicity. Moreover, under this strengthening of protoalgebraicity, and the additional hypothesis that the category of signatures is finite, it was shown that $\mathcal{I}^f$ is also protoalgebraic. On the syntactic side, following along similar lines, we show that, if the category of signatures is finite and $\mathcal{I}$ is syntactically protoalgebraic, with a finite collection of parameter free witnessing transformations, then the Leibniz operator is continuous. We obtain that, under these hypotheses, $\mathcal{I}^f$ is also syntactically protoalgebraic with the same collection of witnessing transformations. To establish a similar result regarding truth equationality, instead of syntactic protoalgebraicity, we need, first, to ensure that the inverse $\Omega^{-1} : \text{ConSys}^*(\mathcal{I}) \rightarrow \text{ThFam}(\mathcal{I})$ is well defined. This happens when, e.g., $\mathcal{I}$ is weakly family algebraizable. We use this hypothesis, together with the finiteness of the category of signatures and the truth equationality of $\mathcal{I}$ via a finite, parameter free collection of witnessing equations, to get that Ω^{-1} is continuous. This also yields that, under the same hypotheses, $\mathcal{I}^f$ is also family truth equational, with the same collection of witnessing equations. These two results combined allow us to show that, if $\mathcal{I}$ has a finite signature category and is syntactically strongly family algebraizable, via a

conjugate pair of finite collections of natural transformations, then $\mathcal{I}^f$ is also syntactically strongly family algebraizable via the same conjugate pair of transformations.

In Section 17.3, we look at *natural finitariness*. A π -institution is finitary if $\mathcal{I} = \mathcal{I}^f$, that is, if, for every signature Σ and all subsets Φ of Σ -sentences,

$$C_\Sigma(\Phi) = \bigcup \{C_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\}.$$

Equivalently, for all signatures Σ and all subsets $\Phi \cup \{\phi\}$ of Σ -sentences, $\phi \in C_\Sigma(\Phi)$ implies that $\phi \in C_\Sigma(\Phi')$, for some $\Phi' \subseteq_f \Phi$. On the other hand, $\mathcal{I}$ is *naturally finitary* if, for all collections μ, ν of natural transformations in N^b , with $|\mu|$ finite,

$$\mu \leq C(\nu) \quad \text{implies} \quad \mu \leq C(\nu'), \text{ for finite } \nu' \subseteq \nu,$$

where the notation $\mu \leq C(\nu)$ means that, for all signatures Σ and all Σ -sentences $\vec{\phi}$, $\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}])$. If a π -institution $\mathcal{I}$ is naturally finitary and syntactically family algebraizable via a finite witnessing family I^b of natural transformations, then every such family possesses a finite witnessing subfamily. Dually, if $\mathcal{I}$ is syntactically strongly family algebraizable, with a naturally finitary equivalent equational π -structure $\mathcal{Q}$ via a finite witnessing family τ^b of equations, then every witnessing family of equations possesses a finite witnessing subfamily. These results allow showing that, for a naturally finitary, syntactically strongly algebraizable π -institution $\mathcal{I}$, every witnessing collection of equations contains a witnessing finite subcollection and that, dually, if $\mathcal{I}$ is syntactically strongly family algebraizable, with naturally finitary equational counterpart $\mathcal{Q}$, then every witnessing collection of natural transformations contains a finite witnessing subcollection. Subject to $\mathcal{I}$ having a finite category of signatures, being finitary and syntactically family algebraizable, if $\mathcal{I}$ has a finite, parameter free witnessing set of transformations, then its equational counterpart $\mathcal{Q}$ may be taken to be finitary. Similarly, if finitariness is replaced by natural finitariness. Dually, under the hypotheses that $\mathcal{I}$ has a finite category of signatures, is syntactically strongly family algebraizable, with a finitary equational counterpart, via a finite, parameter free collection of equations, then $\mathcal{I}$ is finitary. And, similarly, with natural finitariness in lieu of finitariness. The section concludes with a theorem summarizing the results obtained and an accompanying diagram providing a schematic summary. In a nutshell, one deals with a π -institution, with a finite category of signatures, that is syntactically strongly family algebraizable via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$. In case τ^b, I^b are finite, then $\mathcal{I}$ is naturally finitary if and only if $\mathcal{Q}$ is. If $\mathcal{I}$ is naturally finitary, then $\mathcal{Q}$ is naturally finitary if and only if I^b can be taken finite and, dually, if $\mathcal{Q}$ is naturally finitary, then $\mathcal{I}$ is naturally finitary if and only if τ^b can be taken finite. And in each of these three biconditionals, if the equivalent alternatives hold, then all four “finitarity” conditions hold.

17.2 Finitary Companions Revisited

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall from Chapter 9 the construction of the *finitary companion* $\mathcal{I}^f = \langle \mathbf{F}, C^f \rangle$ of $\mathcal{I}$. It is defined, by setting, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \subseteq \mathbf{SEN}^b(\Sigma)$,

$$C_\Sigma^f(\Phi) = \bigcup \{C_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\},$$

where $\subseteq_f$ denotes the finite subset relation. It was shown in Corollary 653 that $\mathcal{I}^f$ is the largest finitary π -institution based on $\mathbf{F}$ that lies below $\mathcal{I}$ in the $\leq$ ordering. Furthermore, even though it is obvious, based on $\mathcal{I}^f \leq \mathcal{I}$, that $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$, Proposition 655 provided a characterization of those sentence families of $\mathbf{F}$ that are theory families of $\mathcal{I}^f$. More concretely, it asserted that $T \in \text{ThFam}(\mathcal{I}^f)$ if and only if it is the union of a directed locally finitely generated collection of theory families of $\mathcal{I}$.

Turning now to the Leibniz hierarchy, some of the semantic aspects of which, in relation to finitariness, were studied in some detail in Chapter 9, it was proven in Lemma 656 that protoalgebraicity is inherited by $\mathcal{I}$ from $\mathcal{I}^f$, i.e., if $\mathcal{I}^f$ is protoalgebraic, then so is $\mathcal{I}$ itself. This is a rather simple consequence of the fact that $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$.

Recall from Chapter 11 the definition of the *reflexive core* $R^\mathcal{I}$ of a π -institution $\mathcal{I}$. It consists of all natural transformations ρ^b in N^b , with two distinguished arguments, having the property that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\rho_\Sigma^b[\phi, \phi] \leq \text{Thm}(\mathcal{I}).$$

It is not very difficult to show that the reflexive core of the finitary companion $\mathcal{I}^f$ of a π -institution $\mathcal{I}$ is included in that of $\mathcal{I}$.

Lemma 1341 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$R^{\mathcal{I}^f} \subseteq R^\mathcal{I}.$$

Proof: Suppose $\rho^b \in R^{\mathcal{I}^f}$ and consider $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. We have

$$\begin{aligned} \rho_\Sigma^b[\phi, \phi] &\leq \text{Thm}(\mathcal{I}^f) \quad (\rho^b \in R^{\mathcal{I}^f}) \\ &\leq \text{Thm}(\mathcal{I}). \quad (\text{Thm}(\mathcal{I}) \in \text{ThFam}(\mathcal{I}^f)) \end{aligned}$$

Thus, by definition, $\rho^b \in R^\mathcal{I}$. It follows that $R^{\mathcal{I}^f} \subseteq R^\mathcal{I}$. ■

Recall that the reflexive core $R^\mathcal{I}$ is said to be *Leibniz* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\langle \phi, \psi \rangle \in \Omega_\Sigma(C(R_\Sigma^\mathcal{I}[\phi, \psi])).$$

From the fact that $R^{\mathcal{I}^f} \subseteq R^\mathcal{I}$ it follows at once that, if $\mathcal{I}^f$ is protoalgebraic and $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$, then $R^\mathcal{I}$ is Leibniz in $\mathcal{I}$.

Proposition 1342 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is protoalgebraic and $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$, then so is $R^{\mathcal{I}}$ in $\mathcal{I}$.*

Proof: Suppose that $\mathcal{I}^f$ is protoalgebraic and $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$. We then have

$$\begin{aligned} \langle \phi, \psi \rangle &\in \Omega_{\Sigma}(C^f(R_{\Sigma}^{\mathcal{I}^f}[\phi, \psi])) && (R^{\mathcal{I}^f} \text{ Leibniz in } \mathcal{I}^f) \\ &\subseteq \Omega_{\Sigma}(C^f(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])) && (\text{Lemma 1341 and hypothesis}) \\ &\subseteq \Omega_{\Sigma}(C(R_{\Sigma}^{\mathcal{I}}[\phi, \psi])). && (\text{Corollary 653 and hypothesis}) \end{aligned}$$

Therefore, $R^{\mathcal{I}}$ is Leibniz in $\mathcal{I}$. ■

We can now show that syntactic protoalgebraicity is inherited by a π -institution $\mathcal{I}$ from its finitary companion $\mathcal{I}^f$. This forms an analog in the syntactic context of Lemma 656.

Theorem 1343 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is syntactically protoalgebraic, then so is $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is syntactically protoalgebraic. By Theorem 805, it is protoalgebraic and its reflexive core $R^{\mathcal{I}^f}$ is Leibniz in $\mathcal{I}^f$. Therefore, by Lemma 656, $\mathcal{I}$ is protoalgebraic and, by Proposition 1342, $R^{\mathcal{I}}$ is Leibniz in $\mathcal{I}$. Therefore, again by Theorem 805, $\mathcal{I}$ is syntactically protoalgebraic. ■

Recalling Theorem 799, which characterizes syntactic protoalgebraicity in terms of the global family modus ponens property of the reflexive core, we derive the following

Corollary 1344 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$, then $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$.*

Proof: If $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$, then, by Theorem 799, $\mathcal{I}^f$ is syntactically protoalgebraic. Thus, by Theorem 1343, $\mathcal{I}$ is syntactically protoalgebraic, whence, again by Theorem 799, applied in the opposite direction, $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$. ■

Alternatively, instead of deriving the implication in Corollary 1344 by applying Theorem 1343, we may prove it first and then use Theorem 799 to establish that syntactic protoalgebraicity of $\mathcal{I}^f$ implies the syntactic protoalgebraicity of $\mathcal{I}$. We outline this reasoning also, at the expense of having to repeat Corollary 1344 and Theorem 1343.

Lemma 1345 (Corollary 1344) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$, then $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$.*

Proof: Suppose $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that

$$\phi \in T_\Sigma \quad \text{and} \quad R_\Sigma^{\mathcal{I}}[\phi, \psi] \leq T.$$

By Lemma 1341, we get

$$\phi \in T_\Sigma \quad \text{and} \quad R_\Sigma^{\mathcal{I}^f}[\phi, \psi] \leq T.$$

But $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$ and $R^{\mathcal{I}^f}$ is assumed to have the global family MP in $\mathcal{I}^f$. Thus, $\psi \in T_\Sigma$. This proves that $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$. ■

Corollary 1346 (Theorem 1343) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is syntactically protoalgebraic, then so is $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is syntactically protoalgebraic. Then, by Theorem 799, $R^{\mathcal{I}^f}$ has the global family MP in $\mathcal{I}^f$. Thus, by Lemma 1345, $R^{\mathcal{I}}$ has the global family MP in $\mathcal{I}$. Hence, again by applying Theorem 799, only now in the reverse direction, $\mathcal{I}$ is syntactically protoalgebraic. ■

A similar work can be undertaken concerning truth equationality, based on an analog of Lemma 657, but referring to family c-reflectivity, which can be proved in a similar fashion as Lemma 657. We now provide the details.

It is straightforward to see, first of all, that family complete reflectivity is also inherited by $\mathcal{I}$ itself from its finitary companion.

Lemma 1347 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is family c-reflective, then so is $\mathcal{I}$.*

Proof: If $\mathcal{I}^f$ is family c-reflective, then, for all $\mathcal{T} \cup \{T'\} \subseteq \text{ThFam}(\mathcal{I}^f)$,

$$\bigcap_{T \in \mathcal{T}} \Omega(T) \leq \Omega(T') \quad \text{implies} \quad \bigcap_{T \in \mathcal{T}} T \leq T'.$$

In particular, the condition holds if quantification is restricted over the collection $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$. Therefore, $\mathcal{I}$ is family c-reflective. ■

It is not very hard either to see that the the Suszko core of the finitary companion $\mathcal{I}^f$ of a π -institution $\mathcal{I}$ is contained in the Suszko core of $\mathcal{I}$ itself, just as was the case with the reflexive core. Recall that the Suszko core $S^{\mathcal{I}}$ of a π -institution $\mathcal{I}$ consists of those natural transformations σ^b in N^b , with a single distinguished argument, such that, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\sigma^b[T] \leq \widetilde{\Omega}^{\mathcal{I}}(T).$$

This means, of course, that, for all $T \in \text{ThFam}(\mathcal{I})$ and all $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{implies} \quad \sigma_\Sigma^b[\phi] \leq \widetilde{\Omega}^{\mathcal{I}}(T).$$

Lemma 1348 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$S^{\mathcal{I}^f} \subseteq S^{\mathcal{I}}.$$

Proof: Suppose that $\sigma^b \in S^{\mathcal{I}^f}$ and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$, such that $\phi \in T_\Sigma$. Then, since $\sigma^b \in S^{\mathcal{I}^f}$ and $T \in \text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$, we get $\sigma_\Sigma^b[\phi] \leq \tilde{\Omega}^{\mathcal{I}^f}(T) \leq \tilde{\Omega}^{\mathcal{I}}(T)$, where the second inclusion follows from the fact that $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$. Therefore, we conclude that $\sigma^b \in S^{\mathcal{I}}$. Hence, $S^{\mathcal{I}^f} \subseteq S^{\mathcal{I}}$. ■

With this result available, we can see that, if $\mathcal{I}^f$ is family c-reflective and its Suszko core is adequate, then the Suszko core of $\mathcal{I}$ is also adequate. Recall that adequacy of the Suszko core $S^{\mathcal{I}}$ means that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\tilde{\Omega}^{\mathcal{I}}(C(\phi)) = \bigcap \{ \Omega(T) : T \in \text{ThFam}(\mathcal{I}) \text{ and } S_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T) \}.$$

Recall also, that the right-to-left inclusion always holds. So the definition is tantamount to the assertion that the left-to-right inclusion also holds.

Proposition 1349 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is family c-reflective and $S^{\mathcal{I}^f}$ is adequate in $\mathcal{I}^f$, then so is $S^{\mathcal{I}}$ in $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is family c-reflective and that $S^{\mathcal{I}^f}$ is adequate. Then, by Theorem 848, $\mathcal{I}^f$ is truth equational, whence, by Theorem 841, for all $T \in \text{ThFam}(\mathcal{I}^f)$,

$$\phi \in T_\Sigma \quad \text{iff} \quad S_\Sigma^{\mathcal{I}^f}[\phi] \leq \Omega(T).$$

Consider $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \mathbf{SEN}^b(\Sigma)$. We have

$$\begin{aligned} \tilde{\Omega}^{\mathcal{I}}(C(\phi)) &= \bigcap \{ \Omega(T) : T \in \text{ThFam}(\mathcal{I}) \text{ and } \phi \in T_\Sigma \} \\ &\quad (\text{Definition of } \tilde{\Omega}^{\mathcal{I}}) \\ &= \bigcap \{ \Omega(T) : T \in \text{ThFam}(\mathcal{I}) \text{ and } S_\Sigma^{\mathcal{I}^f}[\phi] \leq \Omega(T) \} \\ &\quad (\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f) \text{ and displayed equivalence}) \\ &\leq \bigcap \{ \Omega(T) : T \in \text{ThFam}(\mathcal{I}) \text{ and } S_\Sigma^{\mathcal{I}}[\phi] \leq \Omega(T) \}. \\ &\quad (\text{Lemma 1348}) \end{aligned}$$

Thus, by definition, $S^{\mathcal{I}}$ is also adequate in $\mathcal{I}$. ■

We can now show that truth equationality is inherited by a π -institution $\mathcal{I}$ from its finitary companion $\mathcal{I}^f$. This forms an analog of Lemma 1343.

Theorem 1350 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is truth equational, then so is $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is truth equational. By Theorem 848, it is family c-reflective and its Suszko core $S^{\mathcal{I}^f}$ is adequate in $\mathcal{I}^f$. Therefore, by Lemma 1347, $\mathcal{I}$ is family c-reflective and, by Proposition 1349, $S^{\mathcal{I}}$ is adequate in $\mathcal{I}$. Therefore, again by Theorem 848, $\mathcal{I}$ is truth equational. ■

Theorem 841 characterized truth equationality in terms of the solubility property of the Suszko core. In fact, the solubility of the Suszko core is the condition asserting that, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$,

$$S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T) \quad \text{implies} \quad \phi \in T_{\Sigma}.$$

Since the reverse implication always holds, the condition is equivalent to the assertion that, for all $T \in \text{ThFam}(\mathcal{I})$,

$$\phi \in T_{\Sigma} \quad \text{iff} \quad S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T).$$

Corollary 1351 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$, then $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$.*

Proof: If $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$, then, by Theorem 839, $\mathcal{I}^f$ is truth equational. Thus, by Theorem 1350, $\mathcal{I}$ is also truth equational, whence, again by Theorem 839, applied in the opposite direction, $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$. ■

Once more, as was the case with syntactic protoalgebraicity, instead of deriving the implication in Corollary 1351 by applying Theorem 1350, we may prove it first and then use Theorem 839 to establish that truth equationality of $\mathcal{I}^f$ implies truth equationality of $\mathcal{I}$.

Lemma 1352 (Corollary 1351) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$, then $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$.*

Proof: Suppose $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$. Let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$, such that $S_{\Sigma}^{\mathcal{I}}[\phi] \leq \Omega(T)$. Then, by Lemma 1348, we get $S_{\Sigma}^{\mathcal{I}^f}[\phi] \leq \Omega(T)$. But $\text{ThFam}(\mathcal{I}) \subseteq \text{ThFam}(\mathcal{I}^f)$ and $S^{\mathcal{I}^f}$ is assumed to be soluble in $\mathcal{I}^f$. Thus, $\phi \in T_{\Sigma}$. This proves that $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$. ■

Corollary 1353 (Theorem 1350) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is truth equational, then so is $\mathcal{I}$.*

Proof: Suppose $\mathcal{I}^f$ is truth equational. Then, by Theorem 839, $S^{\mathcal{I}^f}$ is soluble in $\mathcal{I}^f$. Thus, by Lemma 1352, $S^{\mathcal{I}}$ is soluble in $\mathcal{I}$. Hence, again by applying Theorem 839, only now in the reverse direction, $\mathcal{I}$ is truth equational. ■

We conclude the section by synthesizing Theorems 1343 and 1350. Recall that a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is syntactically weakly family algebraizable if:

- $\mathcal{I}$ is protoalgebraic;
- $\mathcal{I}$ is family c-reflective;
- $\mathcal{I}$ is $R^{\mathcal{I}}S^{\mathcal{I}}$ -fortified, i.e., $\mathcal{I}$ has a Leibniz reflexive core and an adequate Suszko core.

By Theorem 915, $\mathcal{I}$ is syntactically weakly family algebraizable if and only if it is syntactically protoalgebraic and family truth equational. Thus, we get

Theorem 1354 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}^f$ is syntactically weakly family algebraizable, then so is $\mathcal{I}$.*

Proof: If $\mathcal{I}^f$ is syntactically weakly family algebraizable, then, by Theorem 915, it is syntactically protoalgebraic and family truth equational. Hence, by Theorems 1343 and 1350, $\mathcal{I}$ possesses the same properties. Therefore, applying again Theorem 915 in the reverse direction, we conclude that $\mathcal{I}$ is also syntactically weakly family algebraizable. ■

In Section 9.4, we saw that continuity of the Leibniz operator is one of the key properties when studying finitariness conditions. Lemma 660 showed that, if $\Omega : \text{ThFam}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is continuous, then $\mathcal{I}$ is protoalgebraic. That is asserting the continuity of the Leibniz operator strengthens protoalgebraicity. Additionally, it was proven in Lemma 661 that, if $\mathbf{Sign}^b$ is finite, then continuity of Ω also ensures that the finitary companion $\mathcal{I}^f$ of $\mathcal{I}$ is also protoalgebraic.

We begin, here, our parallel treatment on the syntactic side by showing that, maintaining the finiteness of $\mathbf{Sign}^b$, the condition that $\mathcal{I}$ be syntactically protoalgebraic, with a finite collection of parameter free witnessing transformations $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$, constitutes an additional strengthening on protoalgebraicity, on top of the continuity of Ω .

Proposition 1355 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, with a finite, parameter free collection $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of witnessing transformations, then $\Omega : \text{ThFam}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ is continuous.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution based on $\mathbf{F}$, with a finite, parameter free collection $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of witnessing transformations. Suppose $\{T^i : i \in I\}$ is a directed collection of theory families of $\mathcal{I}$, such that $\bigcup_{i \in I} T^i \in \text{ThFam}(\mathcal{I})$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned}
 \langle \phi, \psi \rangle \in \Omega_{\Sigma}(\bigcup_{i \in I} T^i) & \text{ iff } I_{\Sigma}^b[\phi, \psi] \leq \bigcup_{i \in I} T^i \\
 & \text{ iff } I_{\Sigma}^b[\phi, \psi] \leq T^i, \text{ some } i \in I, \\
 & \text{ iff } \langle \phi, \psi \rangle \in \Omega_{\Sigma}(T^i), \text{ some } i \in I, \\
 & \text{ iff } \langle \phi, \psi \rangle \in \bigcup_{i \in I} \Omega_{\Sigma}(T^i).
 \end{aligned}$$

Note that the second equivalence employs both the fact that $\mathbf{Sign}^b$ is finite and the fact that I^b is finite and parameter free. Thus, $\Omega(\bigcup_{i \in I} T^i) = \bigcup_{i \in I} \Omega(T^i)$ and, hence, Ω is indeed continuous. $\blacksquare$

We next see that this stronger condition than the continuity of the Leibniz operator suffices to ensure that $\mathcal{I}^f$ is also syntactically protoalgebraic, with the same collection of witnessing transformations. Thus, the following proposition may be viewed as a syntactic analog of Lemma 661.

Proposition 1356 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is syntactically protoalgebraic, with a finite and parameter free collection I^b of witnessing transformations, then $\mathcal{I}^f$ is also syntactically protoalgebraic, with the same collection of witnessing transformations.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution, with a finite and parameter free collection I^b of witnessing transformations. Let $T \in \text{ThFam}(\mathcal{I}^f)$. Then, by Proposition 655, there exists a directed locally finitely generated collection $\{T^i : i \in I\} \subseteq \text{ThFam}(\mathcal{I})$, such that $T = \bigcup_{i \in I} T^i$. Now we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned}
\langle \phi, \psi \rangle \in \Omega_\Sigma(T) & \text{ iff } \langle \phi, \psi \rangle \in \Omega_\Sigma(\bigcup_{i \in I} T^i) \\
& \text{ iff } \langle \phi, \psi \rangle \in \bigcup_{i \in I} \Omega_\Sigma(T^i) \quad (\text{Proposition 1355}) \\
& \text{ iff } \langle \phi, \psi \rangle \in \Omega_\Sigma(T^i), \text{ some } i \in I, \\
& \text{ iff } \overset{\leftrightarrow}{I}_\Sigma^b[\phi, \psi] \leq T^i, \text{ some } i \in I, \\
& \text{ iff } \overset{\leftrightarrow}{I}_\Sigma^b[\phi, \psi] \leq \bigcup_{i \in I} T^i \\
& \text{ iff } \overset{\leftrightarrow}{I}_\Sigma^b[\phi, \psi] \leq T.
\end{aligned}$$

Again, note that the one-before-the-last equivalence employs both the fact that $\mathbf{Sign}^b$ is finite and the fact that I^b is finite and parameter free. Therefore, by Corollary 791, $\mathcal{I}^f$ is also syntactically protoalgebraic, with the same collection I^b of witnessing transformations. $\blacksquare$

Suppose, now, that $\mathbf{Sign}^b$ is finite and $\mathcal{I}$ is weakly family algebraizable, so that $\Omega^{-1} : \text{ConSys}^*(\mathcal{I}) \rightarrow \text{ThFam}(\mathcal{I})$ be defined. An analog of Proposition 1355 asserts that, if $\mathcal{I}$ is truth equational, with a finite and parameter free witnessing family $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of equations, then the inverse Leibniz operator Ω^{-1} is continuous. Thus, under these hypotheses, the truth equationality of $\mathcal{I}$ via a finite, parameter free collection of witnessing equations is stronger than the continuity of Ω^{-1} .

Proposition 1357 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a weakly family algebraizable π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is truth equational, with a finite and parameter free collection $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of witnessing equations, then $\Omega^{-1} : \text{ConSys}^*(\mathcal{I}) \rightarrow \text{ThFam}(\mathcal{I})$ is continuous.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a weakly family algebraizable π -institution, which is, in addition, truth equational, with a finite, parameter free collection $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of witnessing equations. Let $\{\theta^i : i \in I\}$ be a directed collection of $\mathcal{I}^*$ -congruence systems, such that $\bigcup_{i \in I} \theta^i \in \text{ConSys}^*(\mathcal{I})$. Now we get, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in \Omega_{\Sigma}^{-1}(\bigcup_{i \in I} \theta^i) & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \bigcup_{i \in I} \theta^i \\ & \text{ iff } \tau_{\Sigma}^b[\phi] \leq \theta^i, \text{ some } i \in I, \\ & \text{ iff } \phi \in \Omega_{\Sigma}^{-1}(\theta^i), \text{ some } i \in I, \\ & \text{ iff } \phi \in \bigcup_{i \in I} \Omega_{\Sigma}^{-1}(\theta^i). \end{aligned}$$

Thus, Ω^{-1} is indeed continuous. ■

Recall from Theorem 663 that given a weakly family algebraizable π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on an algebraic system $\mathbf{F}$ over a finite category of signatures, the continuity of both $\Omega : \text{ThFam}(\mathcal{I}) \rightarrow \text{ConSys}^*(\mathcal{I})$ and $\Omega^{-1} : \text{ConSys}^*(\mathcal{I}) \rightarrow \text{ThFam}(\mathcal{I})$ are sufficient to ensure that $\mathcal{I}^f$ is also weakly family algebraizable. In Propositions 1355 and 1357, by comparison, it was shown that the continuities of Ω and Ω^{-1} are strengthened by assuming, respectively, that $\mathcal{I}$ is syntactically protoalgebraic, with a finite, parameter free witnessing family of transformations, and that $\mathcal{I}$ is family truth equational, with a finite, parameter free witnessing family of equations. We show, next, in an analog of Theorem 663, that imposing these two stronger conditions on $\mathcal{I}$ suffices to ensure that syntactic strong algebraizability transfers from $\mathcal{I}$ to its finitary companion $\mathcal{I}^f$.

Proposition 1358 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution, with a finite, parameter free collection $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of witnessing transformations. If $\mathcal{I}$ is family truth equational, with a finite and parameter free collection τ^b of witnessing equations, then $\mathcal{I}^f$ is also family truth equational, with the same collection of witnessing equations.*

Proof: Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution, with a finite, parameter free collection $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of witnessing transformations, which is family truth equational, with a finite and parameter free collection τ^b of witnessing equations. Let $T \in \text{ThFam}(\mathcal{I}^f)$. Then, by Proposition 655, there exists a directed locally finitely generated collection $\{T^i : i \in I\} \subseteq \text{ThFam}(\mathcal{I})$, such that $T = \bigcup_{i \in I} T^i$. Now we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all

$\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned}
 \phi \in T_\Sigma & \text{ iff } \phi \in \bigcup_{i \in I} T_\Sigma^i \\
 & \text{ iff } \phi \in T_\Sigma^i, \text{ some } i \in I, \\
 & \text{ iff } \tau_\Sigma^b[\phi] \leq \Omega(T^i), \text{ some } i \in I, \\
 & \text{ iff } \tau_\Sigma^b[\phi] \leq \bigcup_{i \in I} \Omega(T^i) \\
 & \text{ iff } \tau_\Sigma^b[\phi] \leq \Omega(\bigcup_{i \in I} T^i) \quad (\text{Proposition 1355}) \\
 & \text{ iff } \tau_\Sigma^b[\phi] \leq \Omega(T).
 \end{aligned}$$

Again, note that the fourth equivalence employs both the fact that $\mathbf{Sign}^b$ is finite and the fact that τ^b is finite and parameter free. We conclude that $\mathcal{I}^f$ is also family truth equational, with the same collection τ^b of witnessing equations. ■

Putting together Propositions we finally obtain the promised analog of Theorem 663.

Theorem 1359 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically strongly family algebraizable π -institution, via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^K$ consisting of finite and parameter free collections of transformations. Then $\mathcal{I}^f$ is also syntactically strongly family algebraizable, via the same conjugate pair of transformations.*

Proof: We simply put together Propositions 1356 and 1358. ■

17.3 Natural Finitarity

This section deals with concepts analogous to those studied in Section 9.4, but in the syntactic, rather than in the semantic, context. In the semantic context, the four key ingredients of our study were the finitariness of the π -institutions involved as well as the continuity of the Leibniz operator and its inverse. Recall that for the inverse to be defined in the context under consideration, the general underlying hypothesis that the π -institution $\mathcal{I}$ be weakly family algebraizable was adhered to. In the present, syntactic, context, we assume that $\mathcal{I}$ is syntactically strongly family algebraizable, that is, syntactically family algebraizable via a conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}^K$, where both $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ and $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ are parameter free witnessing collections of equations and of transformations, respectively. The four notions involved are the properties of $\mathcal{I}$ and $\mathcal{Q}^K$ being naturally finitary, a strengthening of finitariness, and those of τ^b and I^b being finite, also strengthening the continuity of the Leibniz operator and its inverse operator. But let us embark on the developments so as to clarify these introductory remarks and to make the concepts and the details involved precise.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Recall that $\mathcal{I}$ is *finitary* if, for all $\Sigma \in |\mathbf{Sign}^b|$ and

all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, there exists $\Phi' \subseteq_f \Phi$, such that $\phi \in C_\Sigma(\Phi')$. Equivalently, $\mathcal{I}$ is finitary if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \subseteq \text{SEN}^b(\Sigma)$,

$$C_\Sigma(\Phi) = \bigcup \{C_\Sigma(\Phi') : \Phi' \subseteq_f \Phi\}.$$

We say that $\mathcal{I}$ is **naturally finitary** if it is finitary and, in addition, the following condition holds:

(NATFIN) If, for some collections $\mu, \nu : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ of natural transformations in N^b , such that $|\mu| < \infty$, it holds that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}]),$$

then, there exists a finite subset $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu'_\Sigma[\vec{\phi}]).$$

It is not difficult to see that, if $\mathcal{I}$ is naturally finitary, the implication resulting from (NATFIN) by replacing the two inclusions by equalities of closure families also holds.

Lemma 1360 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is naturally finitary, then, for all $\mu, \nu : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu_\Sigma[\vec{\phi}])$, there exists a finite $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu'_\Sigma[\vec{\phi}])$.*

Proof: Suppose $\mathcal{I}$ is naturally finitary and let $\mu, \nu : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu_\Sigma[\vec{\phi}])$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}])$. Thus, by natural finitariness, there exists a finite subset $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $\mu_\Sigma[\vec{\phi}] \leq C(\nu'_\Sigma[\vec{\phi}])$. But, then, we obtain, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$C(\nu_\Sigma[\vec{\phi}]) = C(\mu_\Sigma[\vec{\phi}]) \leq C(\nu'_\Sigma[\vec{\phi}]) \leq C(\nu_\Sigma[\vec{\phi}]).$$

We conclude that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $C(\mu_\Sigma[\vec{\phi}]) = C(\nu'_\Sigma[\vec{\phi}])$. $\blacksquare$

Starting to take advantage of natural finitariness, we show that it allows to draw the conclusion that, in case of syntactic family algebraizability, the existence of a finite witnessing family of transformations ensures that every witnessing family possesses a finite witnessing subfamily. More precisely, we have

Lemma 1361 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a naturally finitary π -institution based on $\mathbf{F}$. Suppose $\mathcal{I}$ is syntactically family algebraizable, with equivalent quasivariety $\mathbf{K}$. If $\mathcal{I}$ has a finite witnessing family $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of transformations, then every witnessing family $J^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ possesses a finite witnessing subfamily J'^b .*

Proof: Suppose that $\mathcal{I}$ is naturally finitary and syntactically family algebraizable, with equivalent quasivariety $\mathbf{K}$. Let $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ be a finite set of witnessing transformations and $J^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ a family of witnessing transformations. By Theorem 914, we get that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$C(I_\Sigma^b[\phi, \psi]) = C(J_\Sigma^b[\phi, \psi]).$$

Since $\mathcal{I}$ is naturally finitary and, by hypothesis, $|I^b| < \infty$, we get, by Lemma 1360, that there exists finite $J'^b \subseteq J^b$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$C(J'_\Sigma^b[\phi, \psi]) = C(I_\Sigma^b[\phi, \psi]).$$

Thus, applying Proposition 906, we conclude that J'^b is also a witnessing family of transformations. ■

Dually, we may also prove a corresponding result concerning the witnessing equations for the truth equationality of $\mathcal{I}$.

Lemma 1362 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically strongly family algebraizable π -institution based on $\mathbf{F}$, with an equivalent naturally finitary equational π -structure $\mathcal{Q}$, via a finite witnessing family $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of equations. Then every witnessing family $\rho^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of equations possesses a finite witnessing subfamily ρ'^b .*

Proof: Follows along the lines of the proof of Lemma 1361. Suppose that $\mathcal{I}$ is syntactically strongly family algebraizable, with an equivalent naturally finitary equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$. Let $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ be a finite set of witnessing equations and $\rho^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ a family of witnessing equations. By Theorem 914, we get that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$D(\tau_\Sigma^b[\phi]) = D(\rho_\Sigma^b[\phi]).$$

Since $\mathcal{Q}$ is naturally finitary and, by hypothesis, $|\tau^b| < \infty$, we get, by Lemma 1360, that there exists finite $\rho'^b \subseteq \rho^b$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$D(\rho'_\Sigma^b[\phi]) = D(\tau_\Sigma^b[\phi]).$$

Thus, applying Proposition 906, we conclude that ρ'^b is also a witnessing family of equations. ■

We now establish a theorem to the effect that, under natural finitariness and syntactic strong family algebraizability, every witnessing family of equations contains a finite witnessing subfamily. This is the first main result in a series of finitariness results that we aim to prove in the present section, with the ultimate goal of obtaining a hierarchy on the syntactic side, analogous to that obtained on the semantic side at the end of Section 9.4.

Theorem 1363 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a naturally finitary, syntactically strongly family algebraizable π -institution, with equivalent equational π -structure $\mathcal{Q}$. Then every witnessing collection $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of equations contains a finite subcollection $\tau'^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$, which is also a witnessing collection.*

Proof: Suppose $\mathcal{I}$ is naturally finitary and syntactically strongly family algebraizable, with equivalent equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$. Let $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ be a collection of witnessing equations. Then, by definition, there exists a collection $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$C(\iota_\Sigma[\phi]) = C(\phi) = C(I^b[\tau_\Sigma^b[\phi]]).$$

Since $\mathcal{I}$ is naturally finitary, there exist finite $I'^b \subseteq I^b$ and $\tau'^b \subseteq \tau^b$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$C(\phi) = C(I'^b[\tau_\Sigma'^b[\phi]]).$$

Thus, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \mathbf{SEN}^b(\Sigma)$,

$$C(\phi) = C(I^b[\tau_\Sigma'^b[\phi]]).$$

Thus, since, by the properties of $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $E \cup \{\phi \approx \psi\} \subseteq \text{Eq}_\Sigma(\mathbf{F})$,

$$\phi \approx \psi \in D_\Sigma(E) \quad \text{iff} \quad I_\Sigma^b[\phi, \psi] \leq C(I_\Sigma^b[E]),$$

we get, by Proposition 906, that τ'^b is a witnessing family of equations. ■

Dually, we may prove that, under syntactic strong family algebraizability and natural finitariness of the equational counterpart $\mathcal{Q}$, every witnessing family of transformations contains a finite witnessing subfamily.

Theorem 1364 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically strongly family algebraizable π -institution, with a naturally finitary equivalent equational π -structure $\mathcal{Q}$. Then every witnessing collection $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of transformations contains a finite subcollection $I'^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$, which is also a witnessing collection.*

Proof: Suppose $\mathcal{I}$ is syntactically strongly family algebraizable, with a naturally finitary equivalent equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$. Let $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ be a collection of witnessing transformations. Then, by definition, there exists a collection $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ in N^b , such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$D(\langle p^{2,0}, p^{2,1} \rangle_\Sigma[\phi, \psi]) = D(\phi \approx \psi) = D(\tau^b[I_\Sigma^b[\phi, \psi]]).$$

Since $\mathcal{I}$ is naturally finitary, there exist finite $I'^b \subseteq I^b$ and $\tau'^b \subseteq \tau^b$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$D(\phi \approx \psi) = D(\tau'^b[I_\Sigma'^b[\phi, \psi]]).$$

Thus, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$D(\phi \approx \psi) = D(\tau^b[I_\Sigma^b[\phi, \psi]]).$$

Thus, since, by the properties of $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \tau_\Sigma^b[\phi] \leq D(\tau_\Sigma^b[\Phi]),$$

we get, by Proposition 906, that I'^b is also a witnessing family of transformations. ■

The following proposition asserts that, under similar hypotheses, but adding finiteness of the signature category, the finitariness of $\mathcal{I}$ and of the witnessing collection I^b imply the finitariness of the equational counterpart $\mathcal{Q}$.

Proposition 1365 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary, syntactically family algebraizable π -institution, with equivalent equational π -structure $\mathcal{Q}$. If $\mathcal{I}$ has a finite witnessing set $I^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ of transformations, then $\mathcal{Q}$ is also finitary.*

Proof: Suppose $\mathcal{I}$ is a finitary π -institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically family algebraizable, with equivalent equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$, and that it has a finite witnessing collection I^b of transformations. Let $\Sigma \in |\mathbf{Sign}^b|$ and $E \cup \{\phi \approx \psi\} \subseteq \text{Eq}_\Sigma(\mathbf{F})$, such that

$$\phi \approx \psi \in D_\Sigma(E).$$

Since I^b is a witnessing collection of transformations,

$$I_\Sigma^b[\phi, \psi] \leq C(I_\Sigma^b[E]).$$

Since $\mathbf{Sign}^b$ is finite and I^b is finite, we get, by the finitariness of $\mathcal{I}$, that there exists finite $E' \subseteq E$, such that $I_\Sigma^b[\phi, \psi] \leq C(I_\Sigma^b[E'])$. Thus, again by the fact that I^b is a set of witnessing transformations, we obtain $\phi \approx \psi \in D_\Sigma(E')$. Thus, $\mathcal{Q}$ is indeed finitary. ■

A similar result can also be established when focus is shifted from finitariness to natural finitariness.

Proposition 1366 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a naturally finitary, syntactically family algebraizable π -institution, with equivalent equational π -structure $\mathcal{Q}$. If $\mathcal{I}$ has a finite witnessing set $I^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ of transformations, then $\mathcal{Q}$ is also naturally finitary.*

Proof: Suppose $\mathcal{I}$ is a naturally finitary π -institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically family algebraizable, with equivalent equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$, and that it has a finite witnessing collection I^b of transformations. By Proposition 1365, we know that $\mathcal{Q}$ is finitary. Let $\mu, \nu : (\mathbf{SEN}^b)^\omega \rightarrow (\mathbf{SEN}^b)^2$ be collections of natural transformations in N^b , with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \mathbf{SEN}^b(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq D(\nu_\Sigma[\vec{\phi}]).$$

Since I^b is a witnessing collection of transformations, we get, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \mathbf{SEN}^b(\Sigma)$,

$$I^b[\mu_\Sigma[\vec{\phi}]] \leq C(I^b[\nu_\Sigma[\vec{\phi}]]).$$

But both μ and I^b are finite and, also, $\mathbf{Sign}^b$ is assumed to be finite. Hence, since $\mathcal{I}$ is naturally finitary, there exists finite $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \mathbf{SEN}^b(\Sigma)$,

$$I^b[\mu_\Sigma[\vec{\phi}]] \leq C(I^b[\nu'_\Sigma[\vec{\phi}]]).$$

Therefore, again by the fact that I^b is a set of witnessing transformations, we obtain, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \mathbf{SEN}^b(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq D(\nu'_\Sigma[\vec{\phi}]).$$

Thus, $\mathcal{Q}$ is indeed naturally finitary. ■

We turn, next, to results dual to those established in Propositions 1365 and 1366. We start with a dual to Proposition 1365 to the effect that, if $\mathcal{Q}$ is finitary and $\mathcal{I}$ has a finite witnessing collection of equations, then $\mathcal{I}$ is itself finitary.

Proposition 1367 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically strongly family algebraizable π -institution, with equivalent equational π -structure $\mathcal{Q}$. If $\mathcal{Q}$ is finitary and $\mathcal{I}$ has a finite witnessing set $\tau^b : \mathbf{SEN}^b \rightarrow (\mathbf{SEN}^b)^2$ of equations, then $\mathcal{I}$ is also finitary.*

Proof: Suppose $\mathcal{I}$ is a π -institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically strongly family algebraizable, with equivalent equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$, such that

$\mathcal{Q}$ is finitary, and that it has a finite witnessing collection τ^b of equations. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that

$$\phi \in C_\Sigma(\Phi).$$

Since τ^b is a witnessing collection of equations,

$$\tau_\Sigma^b[\phi] \leq D(\tau_\Sigma^b[\Phi]).$$

Since $\mathbf{Sign}^b$ is finite and τ^b is finite, we get, by the finitariness of $\mathcal{Q}$, that there exists finite $\Phi' \subseteq \Phi$, such that $\tau_\Sigma^b[\phi] \leq D(\tau_\Sigma^b[\Phi'])$. Thus, again by the fact that τ^b is a set of witnessing equations, we obtain $\phi \in C_\Sigma(\Phi')$. Thus, $\mathcal{I}$ is indeed finitary. ■

A dual of Proposition 1366 addresses the case of natural finitariness.

Proposition 1368 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically strongly family algebraizable π -institution, with equivalent equational π -structure $\mathcal{Q}$. If $\mathcal{Q}$ is naturally finitary and $\mathcal{I}$ has a finite witnessing set $\tau^b : \text{SEN}^b \rightarrow (\text{SEN}^b)^2$ of equations, then $\mathcal{I}$ is also naturally finitary.*

Proof: Suppose $\mathcal{I}$ is a π -institution based on an algebraic system $\mathbf{F}$ over a finite category of signatures. Assume that $\mathcal{I}$ is syntactically strongly family algebraizable, with equivalent equational π -structure $\mathcal{Q} = \langle \mathbf{F}^2, D \rangle$, such that $\mathcal{Q}$ is naturally finitary, and that it has a finite witnessing collection τ^b of equations. Let $\mu, \nu : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ be collections of natural transformations in N^b , with $|\mu| < \infty$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu_\Sigma[\vec{\phi}]).$$

Since τ^b is a witnessing collection of equations, we get, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$\tau^b[\mu_\Sigma[\vec{\phi}]] \leq D(\tau^b[\nu_\Sigma[\vec{\phi}]]).$$

But both μ and τ^b are finite and, also, $\mathbf{Sign}^b$ is assumed to be finite. Hence, since $\mathcal{Q}$ is naturally finitary, there exists finite $\nu' \subseteq \nu$, such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$\tau^b[\mu_\Sigma[\vec{\phi}]] \leq D(\tau^b[\nu'_\Sigma[\vec{\phi}]]).$$

Therefore, again by the fact that τ^b is a set of witnessing equations, we obtain, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$,

$$\mu_\Sigma[\vec{\phi}] \leq C(\nu'_\Sigma[\vec{\phi}]).$$

Thus, $\mathcal{I}$ is naturally finitary. ■

Finally, we present a syntactic analog of Corollary 668, which summarizes the conclusions drawn from the study of the various finitariness properties, at the center of the investigations carried out in the present chapter.

Corollary 1369 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\mathbf{Sign}^b$ finite, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically strongly family algebraizable π -institution, via the conjugate pair $(\tau^b, I^b) : \mathcal{I} \rightleftarrows \mathcal{Q}$.*

- (a) *If both τ^b and I^b are finite, then $\mathcal{I}$ is naturally finitary if and only if $\mathcal{Q}$ is naturally finitary;*
- (b) *If $\mathcal{I}$ is naturally finitary, then $\mathcal{Q}$ is naturally finitary if and only if I^b can be taken to be finite;*
- (c) *If $\mathcal{Q}$ is naturally finitary, then $\mathcal{I}$ is naturally finitary if and only if τ^b can be taken to be finite.*

In each case, if the equivalent alternatives hold, then all four “finitarity” conditions hold.

Proof:

- (a) Suppose both τ^b and I^b are finite. If $\mathcal{I}$ is naturally finitary, then, by Proposition 1366, $\mathcal{Q}$ is also naturally finitary. If, on the other hand, $\mathcal{Q}$ is naturally finitary, then, by Proposition 1368, $\mathcal{I}$ is naturally finitary.
- (b) Assume that $\mathcal{I}$ is naturally finitary. If $\mathcal{Q}$ is naturally finitary, then, by Theorem 1364, I^b may be taken to be finite. If, on the other hand, I^b can be taken to be finite, then, by Proposition 1366, $\mathcal{Q}$ is naturally finitary.
- (c) Assume $\mathcal{Q}$ is naturally finitary. If $\mathcal{I}$ is naturally finitary, then, by Theorem 1363, τ^b may be taken to be finite. If, on the other hand, τ^b may be taken to be finite, then, by Proposition 1368, $\mathcal{I}$ is naturally finitary.

■

In summary, Corollary 1369 establishes the hierarchy depicted below, which parallels in the syntactic context the hierarchy pictured at the end of Chapter 9, concerning the semantic side.

Chapter 18

Properties of Selected Classes

18.1 Protoalgebraic π -Institutions

18.1.1 The Correspondence Theorem

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

Recall that $\mathcal{I}$ is **protoalgebraic** if the Leibniz operator is monotone on theory families, i.e., if, for all $T, T' \in \text{ThFam}(\mathcal{I})$,

$$T \leq T' \quad \text{implies} \quad \Omega(T) \leq \Omega(T').$$

Recall, also, that, by Theorem 175, every protoalgebraic π -institution is stable and that, moreover, by Theorem 179, $\mathcal{I}$ is protoalgebraic if and only if, for all $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \leq T' \quad \text{implies} \quad \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T').$$

The π -institution $\mathcal{I}$ has the **compatibility property** if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \leq T'$, and all $\theta \in \text{ConSys}(\mathbf{A})$,

$$\theta \text{ compatible with } T \quad \text{implies} \quad \theta \text{ compatible with } T'.$$

The π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ has the **filter correspondence property** if, for all $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, and surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with $H : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ an isomorphism,

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle G, \beta \rangle \\ \mathbf{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathbf{B} \end{array}$$

and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\gamma^{-1}(\widehat{\gamma}(T) \vee T') = T \vee \gamma^{-1}(T'),$$

where $\widehat{\gamma}(T) = C^{\mathcal{I}, \mathcal{B}}(\gamma(T))$ is the least $\mathcal{I}$ -filter family on $\mathcal{B}$ that includes $\gamma(T)$.

Our goal is to show that both the compatibility property and the filter correspondence property characterize protoalgebraic π -institutions. We start with a lemma to the effect that, for every $\mathcal{I}$ -filter family T of $\mathcal{A}$, if the kernel of $\langle H, \gamma \rangle$ happens to be compatible with T , then $\gamma(T)$ is already an $\mathcal{I}$ -filter family of $\mathcal{B}$ and, therefore, $\widehat{\gamma}(T) = \gamma(T)$.

Lemma 1370 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$ -algebraic systems, and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with $H : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ an isomorphism. If $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with T , then $\widehat{\gamma}(T) = \gamma(T)$.*

Proof: By definition, $\gamma(T) \leq \widehat{\gamma}(T)$ always holds. To show the reverse inequality, it suffices to show that $\gamma(T)$, under the hypothesis of the compatibility of $\text{Ker}(\langle H, \gamma \rangle)$ with T , is an $\mathcal{I}$ -filter family of $\mathcal{B}$. So assume $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$, and let $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, such that

$$\beta_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq \gamma_{F(\Sigma')}(T_{F(\Sigma')}).$$

This gives

$$\gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi))) \subseteq \gamma_{F(\Sigma')}(T_{F(\Sigma')}).$$

By the postulated compatibility of $\text{Ker}(\langle H, \gamma \rangle)$ with T , we obtain

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq T_{F(\Sigma')}.$$

Since $\phi \in C_\Sigma(\Phi)$ and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) \in T_{F(\Sigma')}.$$

Thus, $\gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\text{SEN}^b(f)(\phi))) \in \gamma_{F(\Sigma')}(T_{F(\Sigma')})$, and, therefore,

$$\beta_{\Sigma'}(\text{SEN}^b(f)(\phi)) \in \gamma_{F(\Sigma')}(T_{F(\Sigma')}).$$

This shows that $\gamma(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$ and, hence, $\widehat{\gamma}(T) = \gamma(T)$. ■

Next, we give an equivalent formulation of the Filter Correspondence Property.

Proposition 1371 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ has the filter correspondence property iff*

for all $\mathcal{I}$ -matrix families $\mathfrak{A} = \langle \mathcal{A}', T' \rangle$, $\mathfrak{A}'' = \langle \mathcal{A}'', T'' \rangle$ and strict surjective matrix morphism $\langle H, \gamma \rangle : \mathfrak{A}' \rightarrow \mathfrak{A}''$, with $H : \mathbf{Sign}' \rightarrow \mathbf{Sign}''$ an isomorphism,

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F', \alpha' \rangle \swarrow & & \searrow \langle F'', \alpha'' \rangle \\ \mathbf{A}' & \xrightarrow{\langle H, \gamma \rangle} & \mathbf{A}'' \end{array}$$

$$T = \gamma^{-1}(\gamma(T)), \quad \text{for all } T' \leq T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}').$$

Proof: Suppose, first, that $\mathcal{I}$ has the Filter Correspondence Property and consider $\mathcal{I}$ -matrix families $\mathfrak{A} = \langle \mathcal{A}', T' \rangle$, $\mathfrak{A}'' = \langle \mathcal{A}'', T'' \rangle$, a strict surjective

matrix morphism $\langle H, \gamma \rangle : \mathfrak{A}' \rightarrow \mathfrak{A}''$, with $H : \mathbf{Sign}' \rightarrow \mathbf{Sign}''$ an isomorphism, and $T' \leq T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}')$. Then we have

$$\begin{aligned} \gamma^{-1}(\gamma(T)) &\leq \gamma^{-1}(\widehat{\gamma}(T) \vee T'') \quad (\gamma(T) \leq \widehat{\gamma}(T)) \\ &= T \vee \gamma^{-1}(T'') \quad (\text{Filter Correspondence}) \\ &= T \vee T' \quad (\langle H, \gamma \rangle \text{ strict}) \\ &= T. \quad (T' \leq T \text{ by hypothesis}) \end{aligned}$$

Thus, the displayed property holds. Assume, conversely, that the displayed property holds. We must show that $\mathcal{I}$ has the Filter Correspondence Property. So suppose that $\mathcal{A} = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$, $\mathcal{A}'' = \langle \mathbf{A}'', \langle F'', \alpha'' \rangle \rangle$ are $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A}' \rightarrow \mathcal{A}''$ a surjective morphism, with $H : \mathbf{Sign}' \rightarrow \mathbf{Sign}''$ an isomorphism, and let $T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}')$ and $T'' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}'')$. Our goal is to show that

$$\gamma^{-1}(\widehat{\gamma}(T') \vee T'') = T' \vee \gamma^{-1}(T'').$$

Notice that $\langle H, \gamma \rangle : \langle \mathcal{A}', \gamma^{-1}(T'') \rangle \rightarrow \langle \mathcal{A}'', T'' \rangle$ is a strict surjective morphism, with H an isomorphism, and $\gamma^{-1}(T'') \leq T' \vee \gamma^{-1}(T'')$. Thus, we fit the setup of the hypothesis, which allows us to conclude that

$$\gamma^{-1}(\gamma(T' \vee \gamma^{-1}(T''))) = T' \vee \gamma^{-1}(T'').$$

So, it suffices, in turn, to show that $\widehat{\gamma}(T') \vee T'' = \gamma(T' \vee \gamma^{-1}(T''))$ and, since, $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with T' (having $\gamma^{-1}(\gamma(T')) = T'$, by hypothesis), it suffices, by Lemma 1370, to show that

$$\gamma(T') \vee T'' = \gamma(T' \vee \gamma^{-1}(T'')).$$

The left to right inclusion is obvious, since $\gamma(T'), T'' \leq \gamma(T' \vee \gamma^{-1}(T''))$. Conversely, note that, taking into account the hypothesis, $T', \gamma^{-1}(T'') \leq \gamma^{-1}(\gamma(T') \vee T'')$. Therefore, $T' \vee \gamma^{-1}(T'') \leq \gamma^{-1}(\gamma(T') \vee T'')$ and, therefore, $\gamma(T' \vee \gamma^{-1}(T'')) \leq \gamma(T') \vee T''$ and, hence, the right to left inclusion also holds. Thus, the Filter Correspondence Property holds. $\blacksquare$

Now we proceed with the formulation and proof of the main theorem.

Theorem 1372 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The following statements are equivalent:*

- (i) $\mathcal{I}$ is protoalgebraic;
- (ii) $\mathcal{I}$ has the compatibility property;
- (iii) $\mathcal{I}$ has the filter correspondence property.

Proof:

- (i) $\Rightarrow$ (ii) Suppose $\mathcal{I}$ is protoalgebraic and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \leq T'$, and $\theta \in \text{ConSys}(\mathbf{A})$, such that θ is compatible with T . Then we have

$$\begin{aligned} \theta &\leq \Omega(T) \quad (\text{by the compatibility of } \theta \text{ with } T) \\ &\leq \Omega(T'). \quad (\text{by protoalgebraicity}) \end{aligned}$$

We conclude that θ is also compatible with T' and, hence, $\mathcal{I}$ has the compatibility property.

- (ii) $\Rightarrow$ (i) Suppose that $\mathcal{I}$ has the compatibility property and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system and $T, T' \in \text{ThFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Then $\Omega(T) \in \text{ConSys}(\mathbf{A})$ and, by the definition of a Leibniz congruence system, it is compatible with T . Now it follows by the compatibility property, that $\Omega(T)$ is also compatible with T' . Hence $\Omega(T) \leq \Omega(T')$. We conclude that $\mathcal{I}$ is protoalgebraic.
- (ii) $\Rightarrow$ (iii) Suppose that $\mathcal{I}$ has the compatibility property and consider $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, a commutative triangle

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle G, \beta \rangle \\ \mathbf{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathbf{B} \end{array}$$

with $H : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ an isomorphism, and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$. Note that it is always the case that

$$T \vee \gamma^{-1}(T') \leq \gamma^{-1}(\widehat{\gamma}(T) \vee T').$$

Thus, it suffices to show that, under the hypothesis of compatibility, the reverse inclusion also holds.

Consider, temporarily, $X \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\gamma^{-1}(T') \leq X$. Since $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with $\gamma^{-1}(T')$, by the postulated compatibility property, it is also compatible with X . Thus, by Lemma 1370, $\widehat{\gamma}(X) = \gamma(X)$. Moreover, we have $T' \leq \gamma(X) = \widehat{\gamma}(X)$.

Now set $X = T \vee \gamma^{-1}(T')$ and reason as follows:

$$\begin{aligned} \gamma^{-1}(\widehat{\gamma}(T) \vee T') &\leq \gamma^{-1}(\widehat{\gamma}(X) \vee T') \quad (T \leq X) \\ &= \gamma^{-1}(\widehat{\gamma}(X)) \quad (T' \leq \widehat{\gamma}(X)) \\ &= \gamma^{-1}(\gamma(X)) \quad (\widehat{\gamma}(X) = \gamma(X)) \\ &= X. \quad (\text{Ker}(\langle H, \gamma \rangle) \text{ compatible with } X) \end{aligned}$$

So we get $\gamma^{-1}(\widehat{\gamma}(T) \vee T') = T \vee \gamma^{-1}(T')$ and $\mathcal{I}$ has the correspondence property.

- (iii)⇒(ii) Suppose that $\mathcal{I}$ has the correspondence property and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, $T, T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, with $T \leq T'$, and $\theta \in \text{ConSys}(\mathbf{A})$, such that θ is compatible with T . We look at the commutative diagram

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F, \pi^\theta \alpha \rangle \\
 \mathbf{A} & \xrightarrow{\langle I, \pi^\theta \rangle} & \mathbf{A}^\theta
 \end{array}$$

and calculate

$$\begin{aligned}
 (\pi^\theta)^{-1}(\widehat{\pi^\theta}(T')) &= (\pi^\theta)^{-1}(\widehat{\pi^\theta}(T') \vee \widehat{\pi^\theta}(T)) \quad (T \leq T') \\
 &= T' \vee (\pi^\theta)^{-1}(\widehat{\pi^\theta}(T)) \quad (\text{correspondence property}) \\
 &\leq T' \vee T \quad (\theta \text{ compatible with } T) \\
 &= T'. \quad (T \leq T')
 \end{aligned}$$

Thus, θ is also compatible with T' and $\mathcal{I}$ has the compatibility property. ■

As a consequence we obtain the *Correspondence Theorem*, which asserts that, under the same hypothesis, $\langle H, \gamma \rangle$ induces an order isomorphism between the principal filter of the lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ generated by $\gamma^{-1}(T')$ and the principal filter of the lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$ generated by T' .

Theorem 1373 (Correspondence Theorem) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Let, also, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ be $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with $H : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ an isomorphism, and $T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$. Then, $Y \mapsto \gamma^{-1}(Y)$, $T' \leq Y \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$, defines an order isomorphism $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'} \cong \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$.*

Proof: $\gamma^{-1} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'} \rightarrow \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$ is well defined by Corollary 55 and it is clearly monotone. Furthermore, $\widehat{\gamma} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')} \rightarrow \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'}$ is also well-defined and monotone. So it suffices to show that, for all $T' \leq Y \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$, $\widehat{\gamma}(\gamma^{-1}(Y)) = Y$ and that, for all $\gamma^{-1}(T') \leq X \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\gamma^{-1}(\widehat{\gamma}(X)) = X$.

First, for $T' \leq Y \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$, since $\langle H, \gamma \rangle$ is surjective, $\gamma(\gamma^{-1}(Y)) = Y$ and, therefore, $\widehat{\gamma}(\gamma^{-1}(Y)) = Y$, since $Y \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})$. For the other equation, if $\gamma^{-1}(T') \leq X \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have,

$$\begin{aligned}
 \gamma^{-1}(\widehat{\gamma}(X)) &= \gamma^{-1}(\widehat{\gamma}(X) \vee T') \quad (\gamma^{-1}(T') \leq X \Rightarrow T' \leq \widehat{\gamma}(X)) \\
 &= X \vee \gamma^{-1}(T') \quad (\text{correspondence property}) \\
 &= X. \quad (\gamma^{-1}(T') \leq X)
 \end{aligned}$$

So $\gamma^{-1} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{B})^{T'} \cong \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\gamma^{-1}(T')}$. ■

18.1.2 The Homomorphism Theorem

We show that, in the case of protoalgebraic π -institutions $\mathcal{I}$, every surjective morphism of $\mathcal{I}$ -matrix families gives rise to a corresponding surjective morphism between their reductions. This establishes a “reduction” functor and, moreover, gives rise to a version of the Homomorphism Theorem of Universal Algebra.

Recall that, given a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ and an $\mathbf{F}$ -matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, we denote by $\mathfrak{A}^*$ the reduction of $\mathfrak{A}$, i.e.,

$$\mathfrak{A}^* = \langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle.$$

Moreover, extending this notation, given $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathbf{SEN}(\Sigma)$, we set

$$\phi^* = \phi/\Omega_{\Sigma}^{\mathcal{A}}(T) \in \mathbf{SEN}^*(\Sigma).$$

Theorem 1374 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Further, let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$, be $\mathbf{F}$ -algebraic systems, $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle$ be $\mathcal{I}$ -matrix families and $\langle H, \gamma \rangle : \mathfrak{A} \rightarrow \mathfrak{A}'$ a surjective morphism. Then, there exists a surjective morphism $\langle H, \gamma^* \rangle : \mathfrak{A}^* \rightarrow \mathfrak{A}'^*$, given, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$, by*

$$\gamma_{\Sigma}^*(\phi^*) = \gamma_{\Sigma}(\phi)^*.$$

Proof: First, we show that, for all $\Sigma \in |\mathbf{Sign}|$, $\gamma_{\Sigma}^* : \mathbf{SEN}^*(\Sigma) \rightarrow \mathbf{SEN}'^*(H(\Sigma))$ is well-defined. Indeed, suppose $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathbf{SEN}(\Sigma)$, such that $\phi^* = \psi^*$, i.e., $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\mathcal{A}}(T)$. Then, since $T \leq \gamma^{-1}(T')$, we get, by protoalgebraicity, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\mathcal{A}}(\gamma^{-1}(T'))$, whence, by Proposition 24, $\langle \phi, \psi \rangle \in \gamma_{\Sigma}^{-1}(\Omega_{H(\Sigma)}^{\mathcal{A}'}(T'))$, and, hence, $\langle \gamma_{\Sigma}(\phi), \gamma_{\Sigma}(\psi) \rangle \in \Omega_{H(\Sigma)}^{\mathcal{A}'}(T')$, or, equivalently, $\gamma_{\Sigma}(\phi)^* = \gamma_{\Sigma}(\psi)^*$.

Next we see that $\gamma^* : \mathbf{SEN}^* \rightarrow \mathbf{SEN}'^* \circ H$ is a natural transformation. To this end, let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi \in \mathbf{SEN}(\Sigma)$. Then we have

$$\begin{array}{ccc} \mathbf{SEN}^*(\Sigma) & \xrightarrow{\gamma_{\Sigma}^*} & \mathbf{SEN}'^*(H(\Sigma)) \\ \mathbf{SEN}^*(f) \downarrow & & \downarrow \mathbf{SEN}'^*(H(f)) \\ \mathbf{SEN}^*(\Sigma') & \xrightarrow{\gamma_{\Sigma'}^*} & \mathbf{SEN}'^*(H(\Sigma')) \end{array}$$

$$\begin{aligned} \mathbf{SEN}'^*(H(f))(\gamma_{\Sigma}^*(\phi^*)) &= \mathbf{SEN}'^*(H(f))(\gamma_{\Sigma}(\phi)^*) \\ &= \mathbf{SEN}'(H(f))(\gamma_{\Sigma}(\phi))^* \\ &= \gamma_{\Sigma'}(\mathbf{SEN}(f)(\phi))^* \\ &= \gamma_{\Sigma'}^*(\mathbf{SEN}(f)(\phi)^*) \\ &= \gamma_{\Sigma'}^*(\mathbf{SEN}^*(f)(\phi^*)). \end{aligned}$$

Surjectivity of $\langle H, \gamma^* \rangle : \mathcal{A}^* \rightarrow \mathcal{A}'^*$ follows from the fact that $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$ is surjective. So it suffices to show that $\langle F', \pi\alpha' \rangle = \langle H, \gamma^* \rangle \circ \langle F, \pi, \alpha \rangle$ and that $\langle H, \gamma^* \rangle : \mathfrak{A}^* \rightarrow \mathfrak{A}'^*$ is a matrix family morphism. The first equation follows from the fact that the upper triangle of the diagram commutes by hypothesis and the rectangle commutes by the definition of $\langle H, \gamma^* \rangle$.

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\
 \mathbf{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathbf{A}' \\
 \langle I, \pi \rangle \downarrow & & \downarrow \langle I, \pi \rangle \\
 \mathbf{A}^* & \xrightarrow{\langle H, \gamma^* \rangle} & \mathbf{A}'^*
 \end{array}$$

To finish the proof, we calculate, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, $\phi^* \in T_\Sigma / \Omega_\Sigma^{\mathcal{A}}(T)$ if and only if, by compatibility, $\phi \in T_\Sigma$ implies, by hypothesis, $\phi \in \gamma_\Sigma^{-1}(T'_{H(\Sigma)})$ if and only if $\gamma_\Sigma(\phi) \in T'_{H(\Sigma)}$ if and only if, by compatibility, $\gamma_\Sigma(\phi)^* \in T'_{H(\Sigma)} / \Omega_{H(\Sigma)}^{\mathcal{A}'}(T')$ if and only if, by the definition of γ^* , $\gamma_\Sigma^*(\phi^*) \in T'_{H(\Sigma)} / \Omega_{H(\Sigma)}^{\mathcal{A}'}(T')$ if and only if $\phi^* \in (\gamma_\Sigma^*)^{-1}(T'_{H(\Sigma)} / \Omega_{H(\Sigma)}^{\mathcal{A}'}(T'))$. ■

We also have the following construction.

Corollary 1375 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Let, also $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$, be $\mathbf{F}$ -algebraic systems, $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ an $\mathcal{I}$ -matrix family and $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle$ a reduced $\mathcal{I}$ -matrix family and $\langle H, \gamma \rangle : \mathfrak{A} \rightarrow \mathfrak{A}'$ a surjective morphism.*

$$\begin{array}{ccc}
 \mathfrak{A} & \xrightarrow{\langle I, \pi \rangle} & \mathfrak{A}^* \\
 & \searrow \langle H, \gamma \rangle & \downarrow \langle H, \gamma^* \rangle \\
 & & \mathfrak{A}'
 \end{array}$$

There exists a unique surjective morphism $\langle H, \gamma^* \rangle : \mathfrak{A}^* \rightarrow \mathfrak{A}'$ that makes the triangle commute.

Proof: By Theorem 1374, there exists a surjective matrix morphism $\langle H, \gamma^* \rangle :$

$\mathfrak{A}^* \rightarrow \mathfrak{A}'^*$, such that the following rectangle commutes:

$$\begin{array}{ccc} \mathfrak{A} & \xrightarrow{\langle I, \pi \rangle} & \mathfrak{A}^* \\ \langle H, \gamma \rangle \downarrow & & \downarrow \langle H, \gamma^* \rangle \\ \mathfrak{A}' & \xrightarrow{\langle I, \pi \rangle} & \mathfrak{A}'^* \end{array}$$

But, by hypothesis, $\mathfrak{A}'$ is reduced, whence $\mathfrak{A}'^* = \mathfrak{A}'$ and $\langle I, \pi \rangle = \langle I, \iota \rangle : \mathfrak{A}' \rightarrow \mathfrak{A}'^*$ is the identity morphism. We now obtain the triangle depicted in the diagram of the statement. ■

Let us denote by $\mathbf{MatFam}(\mathcal{I})$ the category of $\mathcal{I}$ -matrix families with surjective matrix morphisms between them and, similarly, $\mathbf{MatFam}^*(\mathcal{I})$ the category of reduced $\mathcal{I}$ -matrix families with surjective matrix morphisms between them. Then, based on Theorem 1374, we obtain the following functor.

Theorem 1376 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$* : \mathbf{MatFam}(\mathcal{I}) \rightarrow \mathbf{MatFam}^*(\mathcal{I})$$

is a functor. The subcategory $\mathbf{MatFam}^*(\mathcal{I})$ is a reflective subcategory of $\mathbf{MatFam}(\mathcal{I})$ with $*$ a reflector from $\mathbf{MatFam}(\mathcal{I})$ to $\mathbf{MatFam}^*(\mathcal{I})$.

Proof: Given $\mathcal{A} \in \mathbf{MatFam}(\mathcal{I})$, it is easy to see that $\langle I, \iota^* \rangle : \mathcal{A}^* \rightarrow \mathcal{A}^*$ is the identity matrix morphism. For the composition property, assume $\mathfrak{A}, \mathfrak{A}', \mathfrak{A}'' \in \mathbf{MatFam}(\mathcal{I})$, and $\langle G, \beta \rangle : \mathfrak{A} \rightarrow \mathfrak{A}'$, $\langle H, \gamma \rangle : \mathfrak{A}' \rightarrow \mathfrak{A}''$ be matrix morphisms. Then, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \mathbf{SEN}(\Sigma)$,

$$\begin{aligned} (\gamma_{G(\Sigma)} \circ \beta_{\Sigma})^*(\phi^*) &= \gamma_{G(\Sigma)}(\beta_{\Sigma}(\phi))^* \\ &= \gamma_{G(\Sigma)}^*(\beta_{\Sigma}(\phi)^*) \\ &= \gamma_{G(\Sigma)}^*(\beta_{\Sigma}^*(\phi^*)). \end{aligned}$$

Thus, $(\langle H, \gamma \rangle \circ \langle G, \beta \rangle)^* = \langle H, \gamma \rangle^* \circ \langle G, \beta \rangle^*$. Therefore, $* : \mathbf{MatFam}(\mathcal{I}) \rightarrow \mathbf{MatFam}^*(\mathcal{I})$ is a functor.

As far as reflectivity is concerned, for every $\mathfrak{A} \in \mathbf{MatFam}^*(\mathcal{I})$, we consider the natural quotient morphism $\langle I, \pi \rangle : \mathfrak{A} \rightarrow \mathfrak{A}^*$. Given reduced $\mathfrak{B} \in \mathbf{MatFam}^*(\mathcal{I})$ and a surjective morphism $\langle H, \gamma \rangle : \mathfrak{A} \rightarrow \mathfrak{B}$, the surjective morphism $\langle H, \gamma^* \rangle : \mathfrak{A}^* \rightarrow \mathfrak{B}$ of Corollary 1375 is the unique surjective morphism such that the following diagram commutes.

$$\begin{array}{ccc} \mathfrak{A} & \xrightarrow{\langle I, \pi \rangle} & \mathfrak{A}^* \\ & \searrow \langle H, \gamma \rangle & \downarrow \langle H, \gamma^* \rangle \\ & & \mathfrak{B} \end{array}$$

Thus, $\mathbf{MatFam}^*(\mathcal{I})$ is a reflective subcategory of $\mathbf{MatFam}(\mathcal{I})$ with $*$ a reflector from $\mathbf{MatFam}(\mathcal{I})$ to $\mathbf{MatFam}^*(\mathcal{I})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Given an $\mathcal{I}$ -matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, we denote by $\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A})$ the principal filter of the complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ generated by the $\mathcal{I}$ -filter family T :

$$\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}) = \{T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) : T \leq T'\}.$$

Recall that this set is also denoted by $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T$, without explicit reference to the matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$.

The Correspondence Theorem allows us to prove the following.

Theorem 1377 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π -institution based on $\mathbf{F}$. For every $\mathcal{I}$ -matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}) \cong \mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}^*).$$

Proof: By The Correspondence Theorem 1373, with $\mathcal{B} = \mathcal{A}/\Omega^{\mathcal{A}}(T)$, $\langle H, \gamma \rangle = \langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T)$ and $T' = T/\Omega^{\mathcal{A}}(T)$, we get

$$\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))^{T/\Omega^{\mathcal{A}}(T)} \cong \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^{\pi^{-1}(T/\Omega^{\mathcal{A}}(T))}.$$

But this amounts to $\mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}^*) \cong \mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Consider $\mathbf{F}$ -matrix families $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $\mathfrak{B} = \langle \mathcal{B}, T' \rangle$ and a surjective matrix morphism $\langle H, \gamma \rangle : \mathfrak{A} \rightarrow \mathfrak{B}$. By definition, we have $T \leq \gamma^{-1}(T')$. We call $\gamma^{-1}(T')$ the **filter kernel** of $\langle H, \gamma \rangle$. By the inclusion relation above, we can see that, if $\mathfrak{B} \in \mathbf{MatFam}(\mathcal{I})$, then $\gamma^{-1}(T') \in \mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A})$.

Given $\mathfrak{A} = \langle \mathcal{A}, T \rangle$ and $X \in \mathbf{SenFam}(\mathcal{A})$, such that $T \leq X$, we define

$$\mathfrak{A}/X := \langle \mathcal{A}, X \rangle^* = \langle \mathcal{A}/\Omega^{\mathcal{A}}(X), X/\Omega^{\mathcal{A}}(X) \rangle.$$

We call $\mathfrak{A}/X$ the **quotient of $\mathfrak{A}$ by X** . We note that, if $\mathfrak{A} \in \mathbf{MatFam}(\mathcal{I})$, then

$$X \in \mathbf{FiFam}^{\mathcal{I}}(\mathfrak{A}) \quad \text{iff} \quad \mathfrak{A}/X \in \mathbf{MatFam}^*(\mathcal{I}).$$

The following is an analog in the context of $\mathcal{I}$ -matrix families of the Homomorphism Theorem of Universal Algebra.

Theorem 1378 (Homomorphism Theorem) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π -institution based on $\mathbf{F}$. Let also $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, $\mathfrak{A}' = \langle \mathcal{A}', T' \rangle \in \mathbf{MatFam}(\mathcal{I})$ and $\langle H, \gamma \rangle : \mathfrak{A} \rightarrow \mathfrak{A}'$ a surjective morphism.*

- (i) *There exists a strict surjective morphism $\langle H, \gamma' \rangle : \mathfrak{A}/\gamma^{-1}(T') \rightarrow \mathfrak{A}'^*$ with isomorphic components;*
- (ii) *If $X \in \text{FiFam}^T(\mathfrak{A})$ and $X \leq \gamma^{-1}(T')$, then, there exists a surjective morphism $\langle H, \gamma^X \rangle : \mathfrak{A}/X \rightarrow \mathfrak{A}'^*$, such that*

$$\begin{array}{ccc}
 \mathfrak{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathfrak{A}' \\
 \langle I, \pi^X \rangle \downarrow & & \downarrow \langle I, \pi \rangle \\
 \mathfrak{A}/X & \xrightarrow{\langle H, \gamma^X \rangle} & \mathfrak{A}'^*
 \end{array}$$

$$\langle H, \gamma^X \rangle \circ \langle I, \pi^X \rangle = \langle I, \pi \rangle \circ \langle H, \gamma \rangle.$$

Proof:

- (i) First, note that $\gamma^{-1}(T') \leq \gamma^{-1}(T')$, whence, $\langle H, \gamma \rangle : \langle \mathcal{A}, \gamma^{-1}(T') \rangle \rightarrow \mathfrak{A}'$ is also a surjective matrix morphism. Thus, taking into account that $T \leq \gamma^{-1}(T')$, we get, by Theorem 1374, a surjective matrix morphism $\langle H, \gamma^* \rangle : \mathfrak{A}/\gamma^{-1}(T') \rightarrow \mathfrak{A}'^*$, such that the following diagram commutes.

$$\begin{array}{ccc}
 \langle \mathcal{A}, \gamma^{-1}(T') \rangle & \xrightarrow{\langle H, \gamma \rangle} & \mathfrak{A}' \\
 \langle I, \pi \rangle \downarrow & & \downarrow \langle I, \pi \rangle \\
 \mathfrak{A}/\gamma^{-1}(T') & \xrightarrow{\langle H, \gamma^* \rangle} & \mathfrak{A}'^*
 \end{array}$$

It remains to show that, for every $\Sigma \in |\mathbf{Sign}|$,

$$\gamma_\Sigma^* : \text{SEN}^{\gamma^{-1}(T')}(\Sigma) \rightarrow \text{SEN}'^*(H(\Sigma))$$

is a bijection and that $\langle H, \gamma^* \rangle$ is strict. To see that γ_Σ^* is a bijection, let $\phi, \psi \in \text{SEN}(\Sigma)$, such that

$$\gamma_\Sigma^*(\phi/\Omega_\Sigma^A(\gamma^{-1}(T'))) = \gamma_\Sigma^*(\psi/\Omega_\Sigma^A(\gamma^{-1}(T'))).$$

Then, by the commutativity of the rectangle,

$$\gamma_\Sigma(\phi)/\Omega_{H(\Sigma)}^{A'}(T') = \gamma_\Sigma(\psi)/\Omega_{H(\Sigma)}^{A'}(T').$$

This gives that $\langle \phi, \psi \rangle \in \gamma_\Sigma^{-1}(\Omega_{H(\Sigma)}^{A'}(T'))$. Thus, $\langle \phi, \psi \rangle \in \Omega_\Sigma^A(\gamma^{-1}(T'))$ and, hence,

$$\phi/\Omega_\Sigma^A(\gamma^{-1}(T')) = \psi/\Omega_\Sigma^A(\gamma^{-1}(T')).$$

Therefore, $\gamma_\Sigma^* : \text{SEN}^{\gamma^{-1}(T')}(\Sigma) \rightarrow \text{SEN}'^*(H(\Sigma))$ is a bijection, for all $\Sigma \in |\mathbf{Sign}|$.

To prove strictness, assume $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$, such that $\phi/\Omega_\Sigma^A(\gamma^{-1}(T')) \in \gamma_\Sigma^{*-1}(T'_{H(\Sigma)}/\Omega_{H(\Sigma)}^{A'}(T'))$. Then $\gamma_\Sigma^*(\phi/\Omega_\Sigma^A(\gamma^{-1}(T')) \in T'_{H(\Sigma)}/\Omega_{H(\Sigma)}^{A'}(T')$. Hence, by the definition of γ^* , we get $\gamma_\Sigma(\phi)^* \in T'_{H(\Sigma)}/\Omega_{H(\Sigma)}^{A'}(T')$. By compatibility, we obtain $\gamma_\Sigma(\phi) \in T'_{H(\Sigma)}$, whence $\phi \in \gamma_\Sigma^{-1}(T'_{H(\Sigma)})$. This, finally, yields

$$\phi/\Omega_\Sigma^A(\gamma^{-1}(T')) \in \gamma_\Sigma^{-1}(T'_{H(\Sigma)})/\Omega_\Sigma^A(\gamma^{-1}(T')),$$

proving strictness.

(ii) This part is proven by the following diagram chase:

$$\begin{array}{ccccc} \mathfrak{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathfrak{A}' & & \\ \langle I, \pi^X \rangle \downarrow & & \downarrow \langle I, \pi \rangle & & \\ \mathfrak{A}/X & \xrightarrow{\langle I, \pi \rangle} \mathfrak{A}/\gamma^{-1}(T') & \xrightarrow{\langle H, \gamma' \rangle} & \mathfrak{A}'^* & \end{array}$$

where $\langle I, \pi \rangle : \mathfrak{A}/X \rightarrow \mathfrak{A}/\gamma^{-1}(T')$ is the canonical projection morphism, defined because of the hypothesis $X \leq \gamma^{-1}(T')$ and protoalgebraicity, and

$$\langle H, \gamma' \rangle : \mathfrak{A}/\gamma^{-1}(T') \rightarrow \mathfrak{A}'^*$$

is the morphism obtained in Part (i). ■

18.2 Pointed Classes of Algebraic Systems

Proposition 1379 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$, having theorems. Then the following conditions are equivalent:*

- (i) $\mathcal{I}$ is family regular;
- (ii) For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in T_\Sigma$, $T_\Sigma = \phi/\Omega_\Sigma(T)$;
- (iii) For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $t \in \text{Thm}_\Sigma(\mathcal{I})$, $T_\Sigma = t/\Omega_\Sigma(T)$;
- (iv) For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and some $\phi \in T_\Sigma$, $T_\Sigma = \phi/\Omega_\Sigma(T)$;
- (v) For all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and some $t \in \text{Thm}_\Sigma(\mathcal{I})$, $T_\Sigma = t/\Omega_\Sigma(T)$.

Proof:

(i) $\Rightarrow$ (ii) Suppose $\mathcal{I}$ is family regular and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in T_\Sigma$. Then, we have, for all $\psi \in \text{SEN}^b(\Sigma)$,

$$\begin{array}{llll}
 \psi \in T_\Sigma & \text{iff} & \phi, \psi \in T_\Sigma & (\phi \in T_\Sigma) \\
 & \text{iff} & C(\phi, \psi) \leq T & (\text{definition of } C(\phi, \psi)) \\
 & \text{implies} & \Omega_\Sigma(C(\phi, \psi)) \leq \Omega_\Sigma(T) & (\mathcal{I} \text{ protoalgebraic}) \\
 & \text{implies} & \langle \phi, \psi \rangle \in \Omega_\Sigma(T) & (\mathcal{I} \text{ family regular}) \\
 & \text{iff} & \psi \in \phi / \Omega_\Sigma(T). & (\text{definition of } \phi / \Omega_\Sigma(T))
 \end{array}$$

On the other hand, if $\psi \in \phi / \Omega_\Sigma(T)$, then, since $\phi \in T_\Sigma$, by the compatibility of $\Omega(T)$ with T , $\psi \in T_\Sigma$. Thus, we conclude that $T_\Sigma = \phi / \Omega_\Sigma(T)$.

(ii) $\Rightarrow$ (iii) Suppose (ii) holds and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $t \in \text{Thm}_\Sigma(\mathcal{I})$. Then, since $\text{Thm}(\mathcal{I}) \leq T$, we get that $t \in T_\Sigma$ and, hence, by hypothesis, $T_\Sigma = t / \Omega_\Sigma(T)$.

(iii) $\Rightarrow$ (iv) Assume (iii) holds and let $T \in \text{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^b|$. Since $\mathcal{I}$ has theorems, there exists $t \in \text{Thm}_\Sigma(\mathcal{I})$. Then, $t \in T_\Sigma$ and, by hypothesis, $T_\Sigma = t / \Omega_\Sigma(T)$.

(iv) $\Rightarrow$ (v) Assume (iv) holds and let $T \in \text{ThFam}(\mathcal{I})$ and $\Sigma \in |\mathbf{Sign}^b|$. Then, by hypothesis, there exists $\phi \in T_\Sigma$, such that $T_\Sigma = \phi / \Omega_\Sigma(T)$. Moreover, $\mathcal{I}$ has theorems, whence, there exists $t \in \text{Thm}_\Sigma(\mathcal{I})$. Then, we have $t \in T_\Sigma = \phi / \Omega_\Sigma(T)$, whence $\langle \phi, t \rangle \in \Omega_\Sigma(T)$ and, therefore, $T_\Sigma = \phi / \Omega_\Sigma(T) = t / \Omega_\Sigma(T)$.

(v) $\Rightarrow$ (i) Assume that (v) holds and let $T \in \text{ThFam}(\mathcal{I})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in T_\Sigma$. By hypothesis, for some $t \in \text{Thm}_\Sigma(\mathcal{I})$, $T_\Sigma = t / \Omega_\Sigma(T)$. Hence, $\phi, \psi \in t / \Omega_\Sigma(T)$, i.e., $\langle \phi, t \rangle \in \Omega_\Sigma(T)$ and $\langle t, \psi \rangle \in \Omega_\Sigma(T)$. By transitivity, $\langle \phi, \psi \rangle \in \Omega_\Sigma(T)$. Therefore, $\mathcal{I}$ is family regular. ■

We show now that a protoalgebraic family assertional π -institution $\mathcal{I}$ is weakly family algebraizable.

Theorem 1380 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is family assertional, then it is weakly family algebraizable.*

Proof: By Definition 613, protoalgebraicity and family assertionality are equivalent to regular weak family algebraizability. By Proposition 620, this entails weak family algebraizability.

More directly, assume $\mathcal{I}$ is family assertional. Since it is protoalgebraic, by hypothesis, it suffices to show that $\mathcal{I}$ is family injective. To this end, let $T, T' \in \text{ThFam}(\mathcal{I})$, such that $\Omega(T) = \Omega(T')$. Then, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $t \in \text{Thm}_\Sigma(\mathcal{I})$,

$$T_\Sigma = t / \Omega_\Sigma(T) = t / \Omega_\Sigma(T') = T'_\Sigma.$$

Therefore $T = T'$. Hence $\mathcal{I}$ is family injective and, therefore, it is weakly family algebraizable. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a class of $\mathbf{F}$ -algebraic systems. We say that $\mathbf{K}$ is τ^b -**pointed** if, for all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathbf{K}$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}(\Sigma)$,

$$\tau_{\Sigma}^{\mathcal{A}}(\vec{\phi}) = \tau_{\Sigma}^{\mathcal{A}}(\vec{\psi}).$$

$\mathbf{K}$ is called **pointed** if it is τ^b -pointed with respect to some τ^b in N^b .

If a class $\mathbf{K}$ is pointed, then, for every $\mathcal{A} \in \mathbf{K}$, we write $\tau^{\mathcal{A}} = \{\tau_{\Sigma}^{\mathcal{A}}\}_{\Sigma \in |\mathbf{Sign}|}$, where $\tau_{\Sigma}^{\mathcal{A}} := \tau_{\Sigma}^{\mathcal{A}}(\vec{\phi})$, for some $\vec{\phi} \in \text{SEN}(\Sigma)$, this value being independent of the choice of $\vec{\phi} \in \text{SEN}(\Sigma)$.

We focus now on protoalgebraic, family regular π -institutions that have natural theorems. Recall that this means that there exists a natural transformation τ^b in N^b , such that τ^b is evaluated to a theorem in every signature and at all tuples of sentences. Of course, by definition, all π -institutions that fit this description are regularly weakly family algebraizable. We show that for such π -institutions, the class $\text{AlgSys}^*(\mathcal{I})$ of their reduced algebraic systems is a pointed class of $\mathbf{F}$ -algebraic systems, where any natural theorem may serve as the “point”.

Proposition 1381 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic family regular π -institution based on $\mathbf{F}$, having natural theorems. Then, the class $\text{AlgSys}^*(\mathcal{I})$ is a pointed class of $\mathbf{F}$ -algebraic systems.*

Proof: Suppose $\mathcal{I}$ is protoalgebraic and family regular, with a natural theorem $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$, i.e., such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, $\tau_{\Sigma}^b(\vec{\phi}) \in \text{Thm}_{\Sigma}(\mathcal{I})$. By family regularity, we have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$, $\langle \tau_{\Sigma}^b(\vec{\phi}), \tau_{\Sigma}^b(\vec{\psi}) \rangle \in \Omega_{\Sigma}(\text{Thm}(\mathcal{I}))$. Now, let $\mathcal{A} \in \text{AlgSys}^*(\mathcal{I})$. Thus, there exists $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Therefore, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \vec{\psi} \in \text{SEN}^b(\Sigma)$, we get, by what was shown above and protoalgebraicity, and taking into account Lemma 51, $\langle \tau_{\Sigma}^b(\vec{\phi}), \tau_{\Sigma}^b(\vec{\psi}) \rangle \in \Omega_{\Sigma}(\alpha^{-1}(T))$, whence, by Proposition 24, $\langle \tau_{\Sigma}^b(\vec{\phi}), \tau_{\Sigma}^b(\vec{\psi}) \rangle \in \alpha_{\Sigma}^{-1}(\Omega_{F(\Sigma)}^{\mathcal{A}}(T))$. Thus,

$$\langle \alpha_{\Sigma}(\tau_{\Sigma}^b(\vec{\phi})), \alpha_{\Sigma}(\tau_{\Sigma}^b(\vec{\psi})) \rangle \in \Omega_{F(\Sigma)}^{\mathcal{A}}(T) = \Delta_{F(\Sigma)}^{\mathcal{A}},$$

i.e., since τ^b is a natural transformation, $\tau_{F(\Sigma)}^{\mathcal{A}}(\alpha_{\Sigma}(\vec{\phi})) = \tau_{F(\Sigma)}^{\mathcal{A}}(\alpha_{\Sigma}(\vec{\psi}))$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\text{AlgSys}^*(\mathcal{I})$ is a pointed class of $\mathbf{F}$ -algebraic systems, with any natural theorem serving as the “point” natural transformation. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b and $\mathbf{K}$ a τ^b -pointed class of $\mathbf{F}$ -algebraic systems. We say that $\mathbf{K}$

is **relatively point regular** if, for every $\theta, \theta' \in \text{ConSys}^{\mathbf{K}}(\mathcal{F})$,

$$\tau^b/\theta = \tau^b/\theta' \quad \text{implies} \quad \theta = \theta'.$$

It is not difficult to show that the defining property transfers from $\mathbf{K}$ -congruence systems on $\mathcal{F}$ to $\mathbf{K}$ -congruence systems on every $\mathbf{F}$ -algebraic system, under the proviso that $\mathbf{K}$ be an abstract class.

Lemma 1382 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ a natural transformation in N^b , and $\mathbf{K}$ a τ^b -pointed abstract class of $\mathbf{F}$ -algebraic systems. If $\mathbf{K}$ is relatively point regular, then, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and all $\theta, \theta' \in \text{ConSys}^{\mathbf{K}}(\mathcal{A})$,*

$$\tau^{\mathcal{A}}/\theta = \tau^{\mathcal{A}}/\theta' \quad \text{implies} \quad \theta = \theta'.$$

Proof: Suppose $\mathcal{A}$ is an $\mathbf{F}$ -algebraic system, $\theta, \theta' \in \text{ConSys}^{\mathbf{K}}(\mathcal{A})$, such that $\tau^{\mathcal{A}}/\theta = \tau^{\mathcal{A}}/\theta'$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \langle \phi, \tau_{\Sigma}^b \rangle \in \alpha_{\Sigma}^{-1}(\theta_{F(\Sigma)}) & \quad \text{iff} \quad \langle \alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\tau_{\Sigma}^b) \rangle \in \theta_{F(\Sigma)} \\ & \quad \text{iff} \quad \langle \alpha_{\Sigma}(\phi), \tau_{F(\Sigma)}^{\mathcal{A}} \rangle \in \theta_{F(\Sigma)} \\ & \quad \text{iff} \quad \langle \alpha_{\Sigma}(\phi), \tau_{F(\Sigma)}^{\mathcal{A}} \rangle \in \theta'_{F(\Sigma)} \\ & \quad \text{iff} \quad \langle \alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\tau_{\Sigma}^b) \rangle \in \theta'_{F(\Sigma)} \\ & \quad \text{iff} \quad \langle \phi, \tau_{\Sigma}^b \rangle \in \alpha_{\Sigma}^{-1}(\theta'_{F(\Sigma)}). \end{aligned}$$

Thus, $\tau^b/\alpha^{-1}(\theta) = \tau^b/\alpha^{-1}(\theta')$. Since $\mathbf{K}$ is abstract and $\mathcal{A}/\theta, \mathcal{A}/\theta' \in \mathbf{K}$, we get that $\mathcal{F}/\alpha^{-1}(\theta), \mathcal{F}/\alpha^{-1}(\theta') \in \mathbf{K}$. It follows that $\alpha^{-1}(\theta), \alpha^{-1}(\theta') \in \text{ConSys}^{\mathbf{K}}(\mathcal{F})$. Since $\mathbf{K}$ is relatively point regular, by definition, $\alpha^{-1}(\theta) = \alpha^{-1}(\theta')$. Therefore, by surjectivity of $\langle F, \alpha \rangle$, $\theta = \theta'$. ■

Moreover, we can show that, for a protoalgebraic family regular π -institution $\mathcal{I}$, having natural theorems, the associated class $\text{AlgSys}^*(\mathcal{I})$ of its reduced algebraic systems is a relatively point regular class.

Proposition 1383 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic family regular π -institution based on $\mathbf{F}$, having natural theorems. Then, the class $\text{AlgSys}^*(\mathcal{I})$ is a relatively point regular class of $\mathbf{F}$ -algebraic systems.*

Proof: We know, by Proposition 1381, that $\text{AlgSys}^*(\mathcal{I})$ is pointed, with any natural theorem τ^b serving as a “point”. Consider $\theta, \theta' \in \text{ConSys}^*(\mathcal{I})$, such that $\tau^b/\theta = \tau^b/\theta'$. Since $\theta, \theta' \in \text{ConSys}^*(\mathcal{I})$, there exist $T, T' \in \text{ThFam}(\mathcal{I})$, such that $\theta = \Omega(T)$ and $\theta' = \Omega(T')$. But then, since $\mathcal{I}$ is protoalgebraic and family regular, with theorems, we get, by Proposition 1379,

$$\begin{aligned} \theta &= \Omega(T) \\ &= \Omega(\tau^b/\Omega(T)) \quad (\text{Proposition 1379}) \\ &= \Omega(\tau^b/\theta) \\ &= \Omega(\tau^b/\theta') \quad (\text{hypothesis}) \\ &= \Omega(\tau^b/\Omega(T')) \\ &= \Omega(T') \quad (\text{Proposition 1379}) \\ &= \theta'. \end{aligned}$$

Hence $\text{AlgSys}^*(\mathcal{I})$ is indeed relatively point regular. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a τ^b -pointed class of $\mathbf{F}$ -algebraic systems. Define on $\mathbf{F}$ the family $C^{\mathbf{K}, \tau} = \{C_{\Sigma}^{\mathbf{K}, \tau}\}_{\Sigma \in |\mathbf{Sign}^b|}$, by letting, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$C_{\Sigma}^{\mathbf{K}, \tau} : \mathcal{P}(\text{SEN}^b(\Sigma)) \rightarrow \mathcal{P}(\text{SEN}^b(\Sigma)),$$

be given, for all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, by

$$\phi \in C_{\Sigma}^{\mathbf{K}, \tau}(\Phi) \quad \text{iff} \quad \phi \approx \tau_{\Sigma}^b \in C_{\Sigma}^{\mathbf{K}}(\Phi \approx \tau_{\Sigma}^b),$$

i.e., $\phi \in C_{\Sigma}^{\mathbf{K}, \tau}(\Phi)$ if and only if, for all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathbf{K}$, all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq \{\tau_{F(\Sigma')}^{\mathcal{A}}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) = \tau_{F(\Sigma')}^{\mathcal{A}}.$$

In the next proposition, it is shown that $C^{\mathbf{K}, \tau}$ is a closure system on $\mathbf{F}$. In this way the pointed class $\mathbf{K}$ of $\mathbf{F}$ -algebraic systems defines a bona fide π -institution based on $\mathbf{F}$.

Proposition 1384 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a τ^b -pointed class of $\mathbf{F}$ -algebraic systems. $C^{\mathbf{K}, \tau}$ is a closure system on $\mathbf{F}$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$. It is obvious from the definition that

$$C_{\Sigma}^{\mathbf{K}, \tau} : \mathcal{P}(\text{SEN}^b(\Sigma)) \rightarrow \mathcal{P}(\text{SEN}^b(\Sigma))$$

is inflationary and monotone. To show that it is also idempotent, let $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_{\Sigma}^{\mathbf{K}, \tau}(C_{\Sigma}^{\mathbf{K}, \tau}(\Phi))$. Thus, we have, by definition, for all $\mathcal{A} \in \mathbf{K}$, all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(C_{\Sigma}^{\mathbf{K}, \tau}(\Phi))) \subseteq \{\tau_{F(\Sigma')}^{\mathcal{A}}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) = \tau_{F(\Sigma')}^{\mathcal{A}}.$$

But, also by definition, we have, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq \{\tau_{F(\Sigma')}^{\mathcal{A}}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(C_{\Sigma}^{\mathbf{K}, \tau}(\Phi))) \subseteq \{\tau_{F(\Sigma')}^{\mathcal{A}}\}.$$

Therefore, we get that, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq \{\tau_{F(\Sigma')}^{\mathcal{A}}\} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) = \tau_{F(\Sigma')}^{\mathcal{A}},$$

showing that $\phi \in C_{\Sigma}^{\mathbf{K}, \tau}(\Phi)$.

It remains, finally, to show that $C^{\mathbf{K}, \tau}$ is structural. Let $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_{\Sigma}^{\mathbf{K}, \tau}(\Phi)$. Consider $\mathcal{A} \in \mathbf{K}$, such that, for all $\Sigma'' \in |\mathbf{Sign}^b|$ and all $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$,

$$\Sigma \xrightarrow{f} \Sigma' \xrightarrow{g} \Sigma''$$

$\alpha_{\Sigma''}(\text{SEN}^b(g)(\text{SEN}^b(f)(\Phi))) \subseteq \{\tau_{F(\Sigma'')}^A\}$. This gives $\alpha_{\Sigma''}(\text{SEN}^b(gf)(\Phi)) \subseteq \{\tau_{F(\Sigma'')}^A\}$, whence, by hypothesis, $\alpha_{\Sigma''}(\text{SEN}^b(gf)(\phi)) = \tau_{F(\Sigma'')}^A$. Thus, for all $\Sigma'' \in |\mathbf{Sign}^b|$ and all $g \in \mathbf{Sign}^b(\Sigma', \Sigma'')$, $\alpha_{\Sigma''}(\text{SEN}^b(g)(\text{SEN}^b(f)(\phi))) = \tau_{F(\Sigma'')}^A$. We conclude that $\text{SEN}^b(f)(\phi) \in C_{\Sigma'}^{K, \tau}(\text{SEN}^b(f)(\Phi))$ and, therefore, $C^{K, \tau}$ is also structural. ■

Based on Proposition 1384, it makes sense, given an algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a τ^b -pointed class of $\mathbf{F}$ -algebraic systems, to define the **assertional π -institution of $\mathbf{K}$** as the pair

$$\mathcal{I}^{K, \tau} = \langle \mathbf{F}, C^{K, \tau} \rangle.$$

We have seen in Proposition 1383 that, if $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is a protoalgebraic and family regular π -institution, having natural theorems, then its class $\text{AlgSys}^*(\mathcal{I})$ of reduced $\mathbf{F}$ -algebraic systems is a relatively point regular class. We show next, in a form of converse, that if $\mathbf{K}$ is a relatively point regular quasivariety of $\mathbf{F}$ -algebraic systems, then the assertional π -institution $\mathcal{I}^{K, \tau}$, associated with $\mathbf{K}$, is a protoalgebraic family regular π -institution that has natural theorems.

First, we establish possession of natural theorems, under the assumption that $\mathbf{K}$ is pointed.

Proposition 1385 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a pointed class of $\mathbf{F}$ -algebraic systems. Then $\mathcal{I}^{K, \tau}$ has natural theorems.*

Proof: Let $\mathbf{K}$ be a pointed class of $\mathbf{F}$ -algebraic systems. Since $\mathbf{K}$ is pointed, there exists $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , such that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi} \in \text{SEN}^b(\Sigma)$, all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\tau_{F(\Sigma')}^A(\alpha_{\Sigma'}(\text{SEN}^b(f)(\vec{\phi}))) = \tau_{F(\Sigma')}^A.$$

This implies that $\alpha_{\Sigma'}(\tau_{\Sigma'}^b(\text{SEN}^b(f)(\vec{\phi}))) = \tau_{F(\Sigma')}^A$ and, hence, we obtain $\alpha_{\Sigma'}(\text{SEN}^b(f)(\tau_{\Sigma'}^b(\vec{\phi}))) = \tau_{F(\Sigma')}^A$. Thus, by definition, $\tau_{\Sigma'}^b(\vec{\phi}) \in C_{\Sigma'}^{K, \tau}(\emptyset)$ and, therefore, τ^b is a natural theorem. ■

Next, we turn to proving family regularity, again under the assumption of pointedness.

Proposition 1386 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a pointed class of $\mathbf{F}$ -algebraic systems. Then $\mathcal{I}^{K, \tau}$ is a family regular π -institution.*

Proof: Let $\mathbf{K}$ be a pointed class of $\mathbf{F}$ -algebraic systems. We know, by Proposition 1385, that $\mathcal{I}^{K, \tau}$ has a natural theorem τ^b , where τ^b is a point

in $\mathbf{K}$. We show that $\mathcal{I}^{\mathbf{K},\tau}$ is family regular. To this end, let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$. Then, for all $\Sigma' \in |\mathbf{Sign}^b|$ and $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, we have

$$\text{SEN}^b(f)(\phi) \approx \tau_{\Sigma'}^b, \text{SEN}^b(f)(\psi) \approx \tau_{\Sigma'}^b \in C_{\Sigma'}^{\mathbf{K}}(\phi \approx \tau_{\Sigma}^b, \psi \approx \tau_{\Sigma}^b).$$

This implies that, for all σ^b in N^b and all $\bar{\chi} \in \text{SEN}^b(\Sigma')$,

$$\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) \approx \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi}) \in C_{\Sigma'}^{\mathbf{K}}(\phi \approx \tau_{\Sigma}^b, \psi \approx \tau_{\Sigma}^b).$$

Now we get

$$\begin{aligned} \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) &\approx \tau_{\Sigma'}^b \in C_{\Sigma'}^{\mathbf{K}}(\phi \approx \tau_{\Sigma}^b, \psi \approx \tau_{\Sigma}^b) \\ \text{iff } \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi}) &\approx \tau_{\Sigma'}^b \in C_{\Sigma'}^{\mathbf{K}}(\phi \approx \tau_{\Sigma}^b, \psi \approx \tau_{\Sigma}^b). \end{aligned}$$

Hence, by definition,

$$\begin{aligned} \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) &\in C_{\Sigma'}^{\mathbf{K},\tau}(\phi, \psi) \\ \text{iff } \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \bar{\chi}) &\in C_{\Sigma'}^{\mathbf{K},\tau}(\phi, \psi). \end{aligned}$$

Therefore, by Theorem 19, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}(C(\phi, \psi))$. ■

Before establishing protoalgebraicity, we need a couple of lemmas. We show, first, that, if $\mathbf{K}$ is a pointed class, then all theory families of $\mathcal{I}^{\mathbf{K},\tau}$ are fully determined by the corresponding Leibniz class of the point.

Lemma 1387 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with a natural transformation $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and $\mathbf{K}$ a pointed class of $\mathbf{F}$ -algebraic systems. Then, for all $T \in \text{ThFam}(\mathcal{I}^{\mathbf{K},\tau})$,*

$$T = \tau^b / \Omega(T).$$

Proof: Let $\mathbf{K}$ be a pointed class of $\mathbf{F}$ -algebraic systems, $T \in \text{ThFam}(\mathcal{I}^{\mathbf{K},\tau})$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi \in \text{SEN}^b(\Sigma)$.

- Suppose $\phi \in \tau_{\Sigma}^b / \Omega_{\Sigma}(T)$. This means that $\langle \phi, \tau_{\Sigma}^b \rangle \in \Omega_{\Sigma}(T)$. But, by definition, $\tau_{\Sigma}^b \in \text{Thm}_{\Sigma}(\mathcal{I}^{\mathbf{K},\tau}) \subseteq T_{\Sigma}$, whence, by the compatibility property of $\Omega(T)$ with T , we get that $\phi \in T_{\Sigma}$.
- Suppose $\phi \in T_{\Sigma}$. Then $\phi \approx \tau_{\Sigma}^b \in C_{\Sigma}^{\mathbf{K}}(T \approx \tau^b)$. This implies that, for all σ^b in N^b , all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, and all $\bar{\chi} \in \text{SEN}^b(\Sigma')$,

$$\begin{aligned} \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) &\approx \tau_{\Sigma'}^b \in C_{\Sigma'}^{\mathbf{K}}(T \approx \tau^b) \\ \text{iff } \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\tau_{\Sigma}^b), \bar{\chi}) &\approx \tau_{\Sigma'}^b \in C_{\Sigma'}^{\mathbf{K}}(T \approx \tau^b). \end{aligned}$$

This is, by definition, equivalent to the statement that, for all σ^b in N^b , all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, and all $\bar{\chi} \in \text{SEN}^b(\Sigma')$,

$$\sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \bar{\chi}) \in C_{\Sigma'}^{\mathbf{K},\tau}(T) \quad \text{iff} \quad \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\tau_{\Sigma}^b), \bar{\chi}) \in C_{\Sigma'}^{\mathbf{K},\tau}(T).$$

We conclude that $\langle \phi, \tau_{\Sigma}^b \rangle \in \Omega_{\Sigma}(T)$, i.e., that $\phi \in \tau_{\Sigma}^b / \Omega_{\Sigma}(T)$.

Thus, we get that $T = \tau^b/\Omega(T)$. $\blacksquare$

Next, we show that, if $\mathbf{K}$ is a relatively point regular quasivariety, then, for every theory family of $\mathcal{I}^{\mathbf{K},\tau}$, the quotient of $\mathcal{F}$ by the Leibniz congruence system of T , belongs to $\mathbf{K}$ and, therefore, for every theory family T of $\mathcal{I}^{\mathbf{K},\tau}$, the Leibniz congruence system $\Omega(T)$ is a $\mathbf{K}$ -congruence system on $\mathcal{F}$.

Lemma 1388 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with a natural transformation $\tau^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathbf{K}$ a relatively point regular quasivariety of $\mathbf{F}$ -algebraic systems. Then, for all $T \in \text{ThFam}(\mathcal{I}^{\mathbf{K},\tau})$, $\mathcal{F}/\Omega(T) \in \mathbf{K}$.*

Proof: Suppose that $\mathbf{K}$ is a relatively point regular quasivariety of $\mathbf{F}$ -algebraic systems and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi_i, \psi_i \in \mathbf{SEN}^b(\Sigma)$, $i \in I$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that

$$\langle \{\phi_i \approx \psi_i : i \in I\}, \phi \approx \psi \rangle \in \text{GEq}_\Sigma(\mathbf{K}).$$

This is equivalent to the statement $\langle \phi, \psi \rangle \in \Theta_\Sigma^{\mathbf{K},\mathcal{F}}(\{\langle \phi_i, \psi_i \rangle : i \in I\})$. Since $\Theta^{\mathbf{K},\mathcal{F}}(\{\langle \phi_i, \psi_i \rangle : i \in I\}) \in \text{ConSys}^{\mathbf{K}}(\mathcal{F})$ and $\mathbf{K}$ is relatively point regular, $\Theta^{\mathbf{K},\mathcal{F}}(\{\langle \phi_i, \psi_i \rangle : i \in I\})$ is completely determined by its τ^b -equivalence class. So it suffices to consider quasiequations of the form

$$\langle \{\phi_i \approx \tau_\Sigma^b : i \in I\}, \phi \approx \tau_\Sigma^b \rangle \in \text{GEq}_\Sigma(\mathbf{K}).$$

Now, let $T \in \text{ThFam}(\mathcal{I}^{\mathbf{K},\tau})$, such that $\langle \phi_i, \tau_\Sigma^b \rangle \in \Omega_\Sigma(T)$, for all $i \in I$. Then, taking into account Lemma 1387, $\phi_i \in \tau_\Sigma^b/\Omega_\Sigma(T) = T_\Sigma$, for all $i \in I$. Therefore, by definition, $\phi_i \approx \tau_\Sigma^b \in C_\Sigma^{\mathbf{K}}(T \approx \tau^b)$, for all $i \in I$. Since, by hypothesis, $\langle \{\phi_i \approx \tau_\Sigma^b : i \in I\}, \phi \approx \tau_\Sigma^b \rangle \in \text{GEq}_\Sigma(\mathbf{K})$, we get $\phi \approx \tau_\Sigma^b \in C_\Sigma^{\mathbf{K}}(T \approx \tau^b)$, i.e., $\phi \in C_\Sigma^{\mathbf{K},\tau}(T)$. Since $T \in \text{ThFam}(\mathcal{I}^{\mathbf{K},\tau})$, $\phi \in T_\Sigma = \tau_\Sigma^b/\Omega_\Sigma(T)$. Therefore, $\langle \phi, \tau_\Sigma^b \rangle \in \Omega_\Sigma(T)$. We conclude that $\mathcal{F}/\Omega(T)$ satisfies all quasiequations of $\mathbf{K}$ and, hence, since $\mathbf{K}$ is a quasivariety, $\mathcal{F}/\Omega(T) \in \mathbf{K}$. $\blacksquare$

Finally, we establish protoalgebraicity of $\mathcal{I}^{\mathbf{K},\tau}$, under the hypotheses that $\mathbf{K}$ is a relatively point regular quasivariety of $\mathbf{F}$ -algebraic systems.

Proposition 1389 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathbf{K}$ a relatively point regular quasivariety of $\mathbf{F}$ -algebraic systems. Then $\mathcal{I}^{\mathbf{K},\tau}$ is a protoalgebraic π -institution.*

Proof: Let $\mathbf{K}$ be a relatively point regular quasivariety of $\mathbf{F}$ -algebraic systems. We know, by Proposition 1385, that $\mathcal{I}^{\mathbf{K},\tau}$ has a natural theorem τ^b , where τ^b is a point in $\mathbf{K}$, and, by Proposition 1386, that $\mathcal{I}^{\mathbf{K},\tau}$ is a family regular π -institution.

Now we show that $\mathcal{I}^{\mathbf{K},\tau}$ is protoalgebraic. Suppose that $T, T' \in \text{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then, by Lemma 1387, we get $\tau^b/\Omega(T) \leq \tau^b/\Omega(T')$. Since, by Lemma 1388, $\Omega(T)$ and $\Omega(T')$ are $\mathbf{K}$ -congruence systems on $\mathcal{F}$ and $\mathbf{K}$ is

relatively point regular, they are completely determined (generated) by their τ^b -classes and, hence, we get $\Omega(T) \leq \Omega(T')$. Thus, $\mathcal{I}^{K,\tau}$ is protoalgebraic. ■

We show, next, that, for a protoalgebraic family regular π -institution $\mathcal{I}$, having natural theorems, the assertional π -institution of its class $\text{AlgSys}^*(\mathcal{I})$ of reduced $\mathbf{F}$ -algebraic systems coincides with $\mathcal{I}$.

Theorem 1390 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a family regular protoalgebraic π -institution based on $\mathbf{F}$, having a natural theorem τ . Then*

$$\mathcal{I}^{\text{AlgSys}^*(\mathcal{I}),\tau} = \mathcal{I}.$$

Proof: Set, for brevity in the course of this proof, $K := \text{AlgSys}^*(\mathcal{I})$. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. Then

$$\begin{aligned} \phi \in C_{\Sigma}^{K,\tau}(\Phi) & \text{ iff } \phi \approx \tau_{\Sigma}^b \in C_{\Sigma}^K(\Phi \approx \tau_{\Sigma}^b) \\ & \text{ iff for all } T \in \text{ThFam}(\mathcal{I}), \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma'), \\ & \quad \text{SEN}^b(f)(\Phi) \approx \tau_{\Sigma'}^b \in \Omega_{\Sigma'}(T) \\ & \quad \text{implies } \text{SEN}^b(f)(\phi) \approx \tau_{\Sigma'}^b \in \Omega_{\Sigma'}(T) \\ & \text{ iff for all } T \in \text{ThFam}(\mathcal{I}), \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma'), \\ & \quad \text{SEN}^b(f)(\Phi) \in T_{\Sigma'} \text{ implies } \text{SEN}^b(f)(\phi) \in T_{\Sigma'} \\ & \text{ iff } \phi \in C_{\Sigma}(\Phi). \end{aligned}$$

We conclude that $C^{K,\tau} = C$ and, therefore, $\mathcal{I}^{\text{AlgSys}^*(\mathcal{I}),\tau} = \mathcal{I}$. ■

Moreover, starting with a relatively point regular guasivariety of $\mathbf{F}$ -algebraic systems, the class of all reduced $\mathbf{F}$ -algebraic systems of its assertional π -institution coincides with the original class.

Theorem 1391 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , and K a relatively point regular guasivariety of $\mathbf{F}$ -algebraic systems. Then*

$$\text{AlgSys}^*(\mathcal{I}^{K,\tau}) = K.$$

Proof: Let K be a relatively point regular guasivariety of $\mathbf{F}$ -algebraic systems. Assume that $\mathcal{A} \in K$ and consider $\{\tau^{\mathcal{A}}\} := \{\tau_{\Sigma}^{\mathcal{A}}\}_{\Sigma \in |\mathbf{Sign}|} \in \text{SenFam}(\mathcal{A})$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$, all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_{\Sigma}^{K,\tau}(\Phi)$ and $\alpha_{\Sigma}(\Phi) \subseteq \{\tau_{F(\Sigma)}^{\mathcal{A}}\}$, we get, by the definition of $C^{K,\tau}$, $\alpha_{\Sigma}(\phi) = \tau_{F(\Sigma)}^{\mathcal{A}}$. Therefore, $\{\tau^{\mathcal{A}}\} \in \text{ThFam}(\mathcal{I}^{K,\tau})$. Moreover, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\begin{aligned} \langle \phi, \tau_{\Sigma}^{\mathcal{A}} \rangle \in \Omega_{\Sigma}^{\mathcal{A}}(\{\tau^{\mathcal{A}}\}) & \text{ iff } \phi = \tau_{\Sigma}^{\mathcal{A}} \quad (\text{Lemma 1387}) \\ & \text{ iff } \langle \phi, \tau_{\Sigma}^{\mathcal{A}} \rangle \in \Delta_{\Sigma}^{\mathcal{A}}. \end{aligned}$$

Thus, $\tau^{\mathcal{A}}/\Omega^{\mathcal{A}}(\{\tau^{\mathcal{A}}\}) = \tau^{\mathcal{A}}/\Delta^{\mathcal{A}}$. Therefore, by relative point regularity, we obtain $\Omega^{\mathcal{A}}(\{\tau^{\mathcal{A}}\}) = \Delta^{\mathcal{A}}$. This yields $\mathcal{A} \in \text{AlgSys}^*(\mathcal{I}^{K,\tau})$.

Assume, conversely, that $\mathcal{A} \in \text{AlgSys}^*(\mathcal{I}^{K,\tau})$. Then, by definition, there exists $T \in \text{FiFam}^{\mathcal{I}^{K,\tau}}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}$. Suppose that $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that

$$\langle \Phi \approx \tau_{\Sigma}^b, \phi \approx \tau_{\Sigma}^b \rangle \in \text{GEq}_{\Sigma}(\mathbf{K})$$

and $\alpha_{\Sigma}(\Phi) \subseteq \{\tau_{F(\Sigma)}^{\mathcal{A}}\}$. Then, since $T \in \text{FiFam}^{\mathcal{I}^{K,\tau}}(\mathcal{A})$, $\alpha_{\Sigma}(\Phi) \subseteq T_{F(\Sigma)}$. Hence, $\Phi \subseteq \alpha_{\Sigma}^{-1}(T_{F(\Sigma)})$. Since $T \in \text{ThFam}^{\mathcal{I}^{K,\tau}}(\mathcal{A})$, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I}^{K,\tau})$, whence, by Lemma 1387, $\alpha^{-1}(T) = \tau^b/\Omega(\alpha^{-1}(T))$. Thus, we get $\Phi \subseteq \tau_{\Sigma}^b/\Omega_{\Sigma}(\alpha^{-1}(T))$. Hence, $\Phi \approx \tau_{\Sigma}^b \in \Omega_{\Sigma}(\alpha^{-1}(T))$. By Lemma 1388, $\Omega(\alpha^{-1}(T)) \in \text{ConSys}^K(\mathcal{F})$, whence, since $\langle \Phi \approx \tau_{\Sigma}^b, \phi \approx \tau_{\Sigma}^b \rangle \in \text{GEq}_{\Sigma}(\mathbf{K})$, $\phi \approx \tau_{\Sigma}^b \in \Omega_{\Sigma}(\alpha^{-1}(T))$. By Proposition 24, $\phi \approx \tau_{\Sigma}^b \in \alpha_{\Sigma}^{-1}(\Omega_{F(\Sigma)}^{\mathcal{A}}(T))$, i.e., $\alpha_{\Sigma}(\phi) \approx \tau_{F(\Sigma)}^{\mathcal{A}} \in \Omega_{F(\Sigma)}^{\mathcal{A}}(T) = \Delta_{F(\Sigma)}^{\mathcal{A}}$. Thus, $\alpha_{\Sigma}(\phi) = \tau_{F(\Sigma)}^{\mathcal{A}}$. We conclude that $\langle \Phi \approx \tau_{\Sigma}^b, \phi \approx \tau_{\Sigma}^b \rangle \in \text{GEq}_{\Sigma}(\mathcal{A})$. Since $\mathcal{A}$ satisfies all guasiequations in $\text{GEq}(\mathbf{K})$ and $\mathbf{K}$ is, by hypothesis, a guasivariety, we get that $\mathcal{A} \in \mathbf{K}$. Therefore, $\text{AlgSys}^*(\mathcal{I}^{K,\tau}) = \mathbf{K}$. ■

Now we can formulate the main theorems of the section.

Theorem 1392 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is protoalgebraic family regular, with natural theorems, if and only if it is the assertional π -institution of a relatively point regular guasivariety of $\mathbf{F}$ -algebraic systems.*

More precisely, $\mathcal{I}$ is protoalgebraic family regular, with natural theorems, if and only if $\text{AlgSys}^*(\mathcal{I})$ is a relatively point regular guasivariety and $\mathcal{I} = \mathcal{I}^{\text{AlgSys}^*(\mathcal{I}),\tau}$, where τ^b is any natural theorem.

Proof: Suppose $\mathcal{I}$ is protoalgebraic family regular, with natural theorems. Then, by Proposition 1383, $\text{AlgSys}^*(\mathcal{I})$ is a relatively point regular class of $\mathbf{F}$ -algebraic systems and, by protoalgebraicity, Proposition 68 and Theorem ??, it is a guasivariety. Moreover, by Theorem 1390, $\mathcal{I} = \mathcal{I}^{\text{AlgSys}^*(\mathcal{I}),\tau}$.

Assume, conversely, that $\mathcal{I}^{K,\tau}$ is the assertional π -institution of a relatively point regular guasivariety $\mathbf{K}$ of $\mathbf{F}$ -algebraic systems. Then, by Proposition 1386, it is family regular, by Proposition 1389, it is protoalgebraic and, by Proposition 1385, it has natural theorems. ■

Theorem 1393 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\tau^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b . Then, there exists a one to one correspondence between relatively point regular guasivarieties, with point τ^b , and family regular protoalgebraic π -institutions, with a natural theorem τ^b .*

Every relatively point regular guasivariety with point τ^b determines a unique family regular protoalgebraic π -institution with natural theorems, its assertional π -institution.

Every family regular protoalgebraic π -institution with natural theorems is the assertional π -institution of a unique relatively point regular quasivariety, the quasivariety $\text{AlgSys}^*(\mathcal{I})$ of all its reduced $\mathbf{F}$ -algebraic systems.

For each family regular protoalgebraic π -institution, with a natural theorem $\top^b$, we have $\mathcal{I} = \mathcal{I}^{\text{AlgSys}^*(\mathcal{I}), \top}$ and, conversely, for every relatively point regular quasivariety $\mathbf{K}$, with point $\top^b$, we have $\mathbf{K} = \text{AlgSys}^*(\mathcal{I}^{\mathbf{K}, \top})$.

Proof: This is a recap of Theorems 1390 and 1391. ■

Chapter 19

Full Models of π -Institutions

19.1 π -Structures Revisited

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system. An N^b -**structure** is a pair $\mathbb{L} = \langle \mathbf{A}, D \rangle$, where $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ is an N^b -algebraic system and $D : \mathcal{P}\mathbf{SEN} \rightarrow \mathcal{P}\mathbf{SEN}$ is a closure (operator) family (not necessarily a system, i.e., not necessarily structural) on $\mathbf{A}$. An **F-structure** is a pair $\mathbb{L} = \langle \mathcal{A}, D \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathbf{F}$ -algebraic system and $D : \mathcal{P}\mathbf{SEN} \rightarrow \mathcal{P}\mathbf{SEN}$ is a closure family on $\mathcal{A}$.

We give a condition pinpointing exactly when a closure family is a closure system and, as a consequence, when a π -structure becomes a π -institution.

Proposition 1394 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system and $D : \mathcal{P}\mathbf{SEN} \rightarrow \mathcal{P}\mathbf{SEN}$ a closure family on $\mathbf{SEN}$. Then D is a closure system, if and only if, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\mathbf{SEN}(f)^{-1}(\mathcal{D}_{\Sigma'}) \subseteq \mathcal{D}_{\Sigma}$.*

Proof: Suppose, first, that D is structural and let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $X' \subseteq \mathbf{SEN}(\Sigma')$, such that $D_{\Sigma'}(X') = X'$. Then we have

$$\begin{aligned} \mathbf{SEN}(f)(D_{\Sigma}(\mathbf{SEN}(f)^{-1}(X'))) &\subseteq D_{\Sigma'}(\mathbf{SEN}(f)(\mathbf{SEN}(f)^{-1}(X'))) \\ &\subseteq D_{\Sigma'}(X') \\ &= X'. \end{aligned}$$

So $D_{\Sigma}(\mathbf{SEN}(f)^{-1}(X')) \subseteq \mathbf{SEN}(f)^{-1}(X')$ and $\mathbf{SEN}(f)^{-1}(X') \in \mathcal{D}_{\Sigma}$.

Suppose, conversely, that, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\mathbf{SEN}(f)^{-1}(\mathcal{D}_{\Sigma'}) \subseteq \mathcal{D}_{\Sigma}$. Let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}(\Sigma)$, such that $\phi \in D_{\Sigma}(\Phi)$. Let $T' \in \mathcal{D}_{\Sigma'}$, such that $\mathbf{SEN}(f)(\Phi) \subseteq T'$. Thus, $\Phi \subseteq \mathbf{SEN}(f)^{-1}(T')$. By hypothesis, $\mathbf{SEN}(f)^{-1}(T') \in \mathcal{D}_{\Sigma}$, whence, since $\phi \in D_{\Sigma}(\Phi)$ and $\Phi \subseteq \mathbf{SEN}(f)^{-1}(T')$, we get that $\phi \in \mathbf{SEN}(f)^{-1}(T')$ and, therefore, $\mathbf{SEN}(f)(\phi) \in T'$. We conclude that $\mathbf{SEN}(f)(\phi) \in D_{\Sigma'}(\mathbf{SEN}(f)(\Phi))$. Thus, D is a structural closure family on $\mathbf{SEN}$. $\blacksquare$

Let $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$, and consider an N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. We say that

$\langle F, \alpha \rangle$ is a **logical morphism from $\mathbb{L}$ to $\mathbb{L}'$** , denoted $\langle F, \alpha \rangle : \mathbb{L} \dashv \mathbb{L}'$, if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}(\Sigma)$,

$$\phi \in D_{\Sigma}(\Phi) \quad \text{implies} \quad \alpha_{\Sigma}(\phi) \in D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)),$$

or, equivalently, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathbf{SEN}(\Sigma)$,

$$\alpha_{\Sigma}(D_{\Sigma}(\Phi)) \subseteq D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)).$$

Proposition 1395 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$, and consider an N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. $\langle F, \alpha \rangle : \mathbb{L} \dashv \mathbb{L}'$ is a logical morphism if and only if, for every $T' \in \text{ThFam}(\mathbb{L}')$, $\alpha^{-1}(T') \in \text{ThFam}(\mathbb{L})$.*

Proof: Suppose, first, that $\langle F, \alpha \rangle : \mathbb{L} \dashv \mathbb{L}'$ is a logical morphism and let $T' \in \text{ThFam}(\mathbb{L}')$, $\Sigma \in |\mathbf{Sign}|$, $\phi \in \text{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\alpha_\Sigma^{-1}(T'_{F(\Sigma)}))$. Then, we have

$$\begin{aligned} \alpha_\Sigma(\phi) &\in \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(T'_{F(\Sigma)}))) \\ &\subseteq D'_{F(\Sigma)}(\alpha_\Sigma(\alpha_\Sigma^{-1}(T'_{F(\Sigma)}))) \\ &\subseteq D'_{F(\Sigma)}(T'_{F(\Sigma)}) \\ &= T'_{F(\Sigma)}. \end{aligned}$$

Therefore, $\phi \in \alpha_\Sigma^{-1}(T'_{F(\Sigma)})$ and we conclude that $\alpha^{-1}(T') \in \text{ThFam}(\mathbb{L})$.

Suppose, conversely, that, for every $T' \in \text{ThFam}(\mathbb{L}')$, we have $\alpha^{-1}(T') \in \text{ThFam}(\mathbb{L})$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$, such that $\phi \in D_\Sigma(\Phi)$. Then, for all $T' \in \text{ThFam}(\mathbb{L}')$, such that $\alpha_\Sigma(\Phi) \subseteq T'_{F(\Sigma)}$, we get $\Phi \subseteq \alpha_\Sigma^{-1}(T'_{F(\Sigma)})$. Since $\phi \in D_\Sigma(\Phi)$ and, by hypothesis, $\alpha^{-1}(T) \in \text{ThFam}(\mathbb{L})$, we get $\phi \in \alpha_\Sigma^{-1}(T'_{F(\Sigma)})$. Hence, $\alpha_\Sigma(\phi) \in T'_{F(\Sigma)}$. Since $T' \in \text{ThFam}(\mathbb{L}')$ was arbitrary, we conclude that $\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Thus, $\langle F, \alpha \rangle : \mathbb{L} \dashv \mathbb{L}'$ is a logical morphism. ■

Let $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$, and consider an N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. We say that

$\langle F, \alpha \rangle$ is a **biological morphism from $\mathbb{L}$ to $\mathbb{L}'$** , denoted $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$, if $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$ is surjective and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)),$$

or, equivalently, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)$,

$$\alpha_\Sigma(D_\Sigma(\Phi)) = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

Proposition 1396 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$, and consider a surjective N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a biological morphism if and only if $\text{ThFam}(\mathbb{L}) = \alpha^{-1}(\text{ThFam}(\mathbb{L}'))$.*

Proof: Suppose, first, that $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a biological morphism. Then, by Proposition 1395, if $T' \in \text{ThFam}(\mathbb{L}')$, then $\alpha^{-1}(T') \in \text{ThFam}(\mathbb{L})$, whence $\alpha^{-1}(\text{ThFam}(\mathbb{L}')) \subseteq \text{ThFam}(\mathbb{L})$. To show the converse, suppose that $T \in \text{ThFam}(\mathbb{L})$. For every $\Sigma' \in |\mathbf{Sign}'|$, choose $\Sigma \in |\mathbf{Sign}|$, such that $F(\Sigma) = \Sigma'$ and let $T'_{\Sigma'} = D'_{\Sigma'}(\alpha_\Sigma(T_\Sigma))$. Then set

$$T' = \{T'_{\Sigma'}\}_{\Sigma' \in |\mathbf{Sign}'|}.$$

Clearly, $T' \in \text{ThFam}(\mathbb{I}\mathbb{L}')$ and, since $\langle F, \alpha \rangle$ is a biological morphism, $\alpha^{-1}(T') \in \text{ThFam}(\mathbb{I}\mathbb{L})$. But we also have, for all $\Sigma \in |\mathbf{Sign}|$,

$$\alpha_{\Sigma}^{-1}(T'_{F(\Sigma)}) = \alpha_{\Sigma}^{-1}(D'_{F(\Sigma)}(\alpha_{\Sigma}(T_{\Sigma})) = D_{\Sigma}(T_{\Sigma}) = T_{\Sigma}.$$

Therefore, we conclude that $\text{ThFam}(\mathbb{I}\mathbb{L}) \subseteq \alpha^{-1}(\text{ThFam}(\mathbb{I}\mathbb{L}'))$.

Suppose, conversely, that $\text{ThFam}(\mathbb{I}\mathbb{L}) = \alpha^{-1}(\text{ThFam}(\mathbb{I}\mathbb{L}'))$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$. We have $\phi \in D_{\Sigma}(\Phi)$ iff, for all $T \in \text{ThFam}(\mathbb{I}\mathbb{L})$,

$$\Phi \subseteq T_{\Sigma} \quad \text{implies} \quad \phi \in T_{\Sigma},$$

iff, for all $T' \in \text{ThFam}(\mathbb{I}\mathbb{L}')$,

$$\Phi \subseteq \alpha_{\Sigma}^{-1}(T'_{F(\Sigma)}) \quad \text{implies} \quad \phi \in \alpha_{\Sigma}^{-1}(T'_{F(\Sigma)}),$$

iff, for all $T' \in \text{ThFam}(\mathbb{I}\mathbb{L}')$,

$$\alpha_{\Sigma}(\Phi) \subseteq T'_{F(\Sigma)} \quad \text{implies} \quad \alpha_{\Sigma}(\phi) \in T'_{F(\Sigma)},$$

iff $\alpha_{\Sigma}(\phi) \in D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi))$. Therefore, $\langle F, \alpha \rangle$ is a biological morphism. $\blacksquare$

Let $\mathbb{I}\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{I}\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$, and consider an N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. We say that

$\langle F, \alpha \rangle$ is an α -**isomorphism from $\mathbb{I}\mathbb{L}$ to $\mathbb{I}\mathbb{L}'$** , denoted $\langle F, \alpha \rangle : \mathbb{I}\mathbb{L} \vdash^{\alpha} \mathbb{I}\mathbb{L}'$, if it is a biological morphism $\langle F, \alpha \rangle : \mathbb{I}\mathbb{L} \vdash \mathbb{I}\mathbb{L}'$, such that, for all $\Sigma \in |\mathbf{Sign}|$, $\alpha_{\Sigma} : \text{SEN}(\Sigma) \rightarrow \text{SEN}'(F(\Sigma))$ is a bijection.

Finally, $\langle F, \alpha \rangle : \mathbb{I}\mathbb{L} \rightarrow \mathbb{I}\mathbb{L}'$ is an **isomorphism**, denoted $\langle F, \alpha \rangle : \mathbb{I}\mathbb{L} \cong \mathbb{I}\mathbb{L}'$, if it is an α -isomorphism and $F : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ is also an isomorphism.

In most instances, when a result holds for $F : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ an isomorphism, we will formulate it, for simplicity, for the identity functor $I_{\mathbf{Sign}} : \mathbf{Sign} \rightarrow \mathbf{Sign}$, which will be sufficient for most of our purposes.

The following is an important characterization result for biological morphisms containing many equivalent formulations.

Given an N^b -structure $\mathbb{I}\mathbb{L} = \langle \mathbf{A}, D \rangle$, a congruence system $\theta \in \text{ConSys}(\mathbf{A})$ is called a **logical congruence system of $\mathbb{I}\mathbb{L}$** if it is compatible with every theory family of $\mathbb{I}\mathbb{L}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,

$$\langle \phi, \psi \rangle \in \theta_{\Sigma} \quad \text{implies} \quad D_{\Sigma}(\phi) = D_{\Sigma}(\psi).$$

If this is the case, we write $\theta \in \text{ConSys}(\mathbb{I}\mathbb{L})$.

Proposition 1397 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{I}\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{I}\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$, and consider a surjective N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. Then the following are equivalent:*

- (i) $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a biological morphism;
- (ii) For all $\Sigma \in |\mathbf{Sign}|$, $\Phi \subseteq \text{SEN}(\Sigma)$, $D_\Sigma(\Phi) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)))$;
- (iii) For all $\Sigma \in |\mathbf{Sign}|$, $\Phi \subseteq \text{SEN}(\Sigma)$, $\alpha_\Sigma(D_\Sigma(\Phi)) = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$ and $\text{Ker}(\langle F, \alpha \rangle) \in \text{ConSys}(\mathbb{L})$;
- (iv) For all $\Sigma \in |\mathbf{Sign}|$, $\Psi \subseteq \text{SEN}'(F(\Sigma))$, $D'_{F(\Sigma)}(\Psi) = \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\Psi)))$ and $\text{Ker}(\langle F, \alpha \rangle) \in \text{ConSys}(\mathbb{L})$;
- (v) For all $\Sigma \in |\mathbf{Sign}|$, $\text{Th}_{F(\Sigma)}(\mathbb{L}') = \alpha_\Sigma(\text{Th}_\Sigma(\mathbb{L}))$ and, also, $\text{Ker}(\langle F, \alpha \rangle) \in \text{ConSys}(\mathbb{L})$;
- (vi) $\text{ThFam}(\mathbb{L}) = \alpha^{-1}(\text{ThFam}(\mathbb{L}'))$.

Proof:

- (i) $\Rightarrow$ (ii) Suppose $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$. Then, we have

$$\begin{aligned} \phi \in D_\Sigma(\Phi) & \text{ iff } \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \\ & \text{ iff } \phi \in \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))). \end{aligned}$$

We conclude that $D_\Sigma(\Phi) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)))$.

- (ii) $\Rightarrow$ (iii) Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \subseteq \text{SEN}(\Sigma)$. Then, by the hypothesis (ii), $D_\Sigma(\Phi) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)))$, whence, by surjectivity of $\langle F, \alpha \rangle$, $\alpha_\Sigma(D_\Sigma(\Phi)) = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. For the second claim, suppose $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Then

$$\alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\phi))) = \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\psi))).$$

Thus, by hypothesis, $D_\Sigma(\phi) = D_\Sigma(\psi)$. It follows that $\text{Ker}(\langle F, \alpha \rangle)$ is a logical congruence system of $\mathbb{L}$.

- (iii) $\Rightarrow$ (iv) Let $\Sigma \in |\mathbf{Sign}|$ and $\Psi \in \text{SEN}'(F(\Sigma))$. Then we have

$$\begin{aligned} D'_{F(\Sigma)}(\Psi) &= D'_{F(\Sigma)}(\alpha_\Sigma(\alpha_\Sigma^{-1}(\Psi))) \\ &= \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\Psi))). \end{aligned}$$

- (iv) $\Rightarrow$ (v) Let $\Sigma \in |\mathbf{Sign}|$ and assume, first, that $T' \in \text{Th}_{F(\Sigma)}(\mathbb{L}')$. Then, we have

$$T' = D'_{F(\Sigma)}(T') = \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(T'))) \in \alpha_\Sigma(\text{Th}_\Sigma(\mathbb{L})).$$

Suppose, conversely, that $T \in \text{Th}_\Sigma(\mathbb{L})$. Then, we have

$$\begin{aligned} D'_{F(\Sigma)}(\alpha_\Sigma(T)) &= \alpha_\Sigma(D_\Sigma(\alpha_\Sigma^{-1}(\alpha_\Sigma(T)))) \\ &= \alpha_\Sigma(D_\Sigma(T)) \\ &= \alpha_\Sigma(T). \end{aligned}$$

Therefore, $\alpha_\Sigma(T) \in \text{Th}_{F(\Sigma)}(\mathbb{L}')$.

(v) $\Rightarrow$ (vi) It suffices to show that, for all $\Sigma \in |\mathbf{Sign}|$, $\text{Th}_\Sigma(\mathbb{L}) = \alpha_\Sigma^{-1}(\text{Th}_{F(\Sigma)}(\mathbb{L}'))$.

Suppose, first, $T \in \text{Th}_\Sigma(\mathbb{L})$. Then, by hypothesis, $\alpha_\Sigma(T) \in \text{Th}_{F(\Sigma)}(\mathbb{L}')$. But, since $\text{Ker}(\langle F, \alpha \rangle) \in \text{ConSys}(\mathbb{L})$, we now get

$$T = \alpha_\Sigma^{-1}(\alpha_\Sigma(T)) \in \alpha_\Sigma^{-1}(\text{Th}_{F(\Sigma)}(\mathbb{L}')).$$

Therefore, $\text{Th}_\Sigma(\mathbb{L}) \subseteq \alpha_\Sigma^{-1}(\text{Th}_{F(\Sigma)}(\mathbb{L}'))$.

Suppose, conversely, $T' \in \text{Th}_{F(\Sigma)}(\mathbb{L}')$. Then, by hypothesis, there exists $T \in \text{Th}_\Sigma(\mathbb{L})$, such that $T' = \alpha_\Sigma(T)$. Thus, since $\text{Ker}(\langle F, \alpha \rangle) \in \text{ConSys}(\mathbb{L})$, we now get

$$\alpha_\Sigma^{-1}(T') = \alpha_\Sigma^{-1}(\alpha_\Sigma(T)) = T \in \text{Th}_\Sigma(\mathbb{L}).$$

We conclude that $\alpha_\Sigma^{-1}(\text{Th}_{F(\Sigma)}(\mathbb{L}')) \subseteq \text{Th}_\Sigma(\mathbb{L})$ and, hence, $\text{ThFam}(\mathbb{L}) = \alpha^{-1}(\text{ThFam}(\mathbb{L}'))$.

(vi) $\Rightarrow$ (i) This is one part of Proposition 1396. ■

A consequence of the preceding characterization is that, when the categories of signatures of the N^b -structures that are connected via a biological morphism are isomorphic, then the complete lattices of their theory families are order isomorphic.

Proposition 1398 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ and consider a surjective N^b -algebraic system morphism $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$. Then $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a biological morphism if and only if, for all $\Sigma \in |\mathbf{Sign}|$, $\alpha_\Sigma : \text{Th}_\Sigma(\mathbb{L}) \rightarrow \text{Th}_{F(\Sigma)}(\mathbb{L}')$ is an order isomorphism.*

Proof: First, by Part (v) of Proposition 1397, α is a well defined surjection from $\text{Th}_\Sigma(\mathbb{L})$ onto $\text{Th}_{F(\Sigma)}(\mathbb{L}')$. Second, by Part (ii) of Proposition 1397, it is an injection. Therefore, it is a bijection, whose inverse, also by Part (ii) of Proposition 1397, is α_Σ^{-1} . That both α_Σ and α_Σ^{-1} are order preserving is straightforward.

Conversely, note that Part (vi) of Proposition 1397 is automatically satisfied in case $\alpha_\Sigma : \text{Th}_\Sigma(\mathbb{L}) \rightarrow \text{Th}_{F(\Sigma)}(\mathbb{L}')$ is an order isomorphism, for all $\Sigma \in |\mathbf{Sign}|$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system and consider an N^b -algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$. Extending the concept and notation from the framework of closure systems and π -institutions, given two closure families D and D' on $\mathbf{A}$ and corresponding N^b -structures $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}, D' \rangle$, we write $D \leq D'$ and $\mathbb{L} \leq \mathbb{L}'$ to signify that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)$,

$$D_\Sigma(\Phi) \subseteq D'_\Sigma(\Phi).$$

Under this ordering, the collection of all closure families on the algebraic system $\mathbf{A}$ forms a complete lattice, which will be denoted by

$$\mathbf{ClFam}(\mathbf{A}) = \langle \mathbf{ClFam}(\mathbf{A}), \leq \rangle.$$

Given $D \in \mathbf{ClFam}(\mathbf{A})$ and corresponding N^b -structure $\mathbb{L} = \langle \mathbf{A}, D \rangle$, we write $\mathbf{ClFam}(\mathbb{L}) = \mathbf{ClFam}^D(\mathbf{A})$ to denote the principal filter of $\mathbf{ClFam}(\mathbf{A})$ generated by D , i.e., we set

$$\mathbf{ClFam}(\mathbb{L}) = \{D' \in \mathbf{ClFam}(\mathbf{A}) : D \leq D'\}.$$

Then, we have the following corollary, expressed partially in terms of the closed set families corresponding in the standard way with closure operator families.

Corollary 1399 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$. If $\langle I, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$, where $I : \mathbf{Sign} \rightarrow \mathbf{Sign}'$ is the identity functor, is a biological morphism, then*

$$\mathcal{T} \mapsto \alpha(\mathcal{T}) := \{\alpha(T) : T \in \mathcal{T}\}$$

is an isomorphism between $\mathbf{ClFam}(\mathbb{L})$ and $\mathbf{ClFam}(\mathbb{L}')$.

Proof: Directly from Proposition 1398. ■

Recall that given an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and a closure family $\mathcal{D}$ on $\mathbf{A}$, with corresponding N^b -structure $\mathbb{L} = \langle \mathbf{A}, \mathcal{D} \rangle$, and $T \in \mathbf{ThFam}(\mathbb{L})$, we denote by $\mathbb{L}^T = \langle \mathbf{A}, \mathcal{D}^T \rangle$ the N^b -structure whose theory families are those closure families of $\mathbb{L}$ that contain T . Moreover, we denote by $\tilde{\Omega}(\mathbb{L}^T)$ or $\tilde{\Omega}^{\mathbf{A}}(\mathcal{D}^T)$ the Tarski congruence system of $\mathbb{L}^T$, i.e., the large congruence system on $\mathbf{A}$ compatible with all theory families in $\mathcal{D}^T$.

Connecting Tarski congruence systems and biological morphisms, we obtain the following:

Proposition 1400 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$. If $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a biological morphism, then, for all $T' \in \mathbf{ThFam}(\mathbb{L}')$,*

$$\alpha^{-1}(\tilde{\Omega}(\mathbb{L}'^{T'})) = \tilde{\Omega}(\mathbb{L}^{\alpha^{-1}(T')}).$$

Proof: We have

$$\begin{aligned} \alpha^{-1}(\tilde{\Omega}(\mathbb{L}'^{T'})) &= \alpha^{-1}(\cap \{\Omega^{\mathbf{A}'}(T'') : T' \leq T'' \in \mathbf{ThFam}(\mathbb{L}')\}) \\ &= \cap \{\alpha^{-1}(\Omega^{\mathbf{A}'}(T'')) : T' \leq T'' \in \mathbf{ThFam}(\mathbb{L}')\} \\ &= \cap \{\Omega^{\mathbf{A}}(\alpha^{-1}(T'')) : T' \leq T'' \in \mathbf{ThFam}(\mathbb{L}')\} \\ &= \cap \{\Omega^{\mathbf{A}}(T) : \alpha^{-1}(T') \leq T \in \mathbf{ThFam}(\mathbb{L})\} \\ &= \tilde{\Omega}(\mathbb{L}^{\alpha^{-1}(T')}). \end{aligned}$$
■

In particular, we obtain

Corollary 1401 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbb{I} = \langle \mathbf{A}, D \rangle$ and $\mathbb{I}' = \langle \mathbf{A}', D' \rangle$ be two N^b -structures, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$. If $\langle F, \alpha \rangle : \mathbb{I} \vdash \mathbb{I}'$ is a biological morphism, then*

$$\alpha^{-1}(\tilde{\Omega}(\mathbb{I}')) = \tilde{\Omega}(\mathbb{I}).$$

Proof: By Proposition 1398, we have that $\alpha^{-1}(\text{Thm}(\mathbb{I}')) = \text{Thm}(\mathbb{I})$. So the result follows by applying Proposition 1400 with $T' = \text{Thm}(\mathbb{I}')$. ■

We close the section by proving that two important properties of N^b -structures are preserved under biological morphisms.

First, we show that finitariness is preserved across biological morphisms. Given a base algebraic system $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$, an N^b -algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and an N^b -structure $\mathbb{I} = \langle \mathbf{A}, D \rangle$, we say that $\mathbb{I}$ is **finitary** if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \mathbf{SEN}(\Sigma)$,

$$D_\Sigma(\Phi) = \bigcup \{D_\Sigma(\Psi) : \Psi \subseteq_f \Phi\},$$

where $\subseteq_f$ denoted the finite subset relation.

Proposition 1402 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ N^b -algebraic systems, $\mathbb{I} = \langle \mathbf{A}, D \rangle$, $\mathbb{I}' = \langle \mathbf{A}', D' \rangle$ N^b -structures, based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{I} \vdash \mathbb{I}'$ a biological morphism. Then $\mathbb{I}$ is finitary if and only if $\mathbb{I}'$ is finitary.*

Proof: Since $\langle F, \alpha \rangle : \mathbb{I} \vdash \mathbb{I}'$ is a biological morphism, it is surjective and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{iff} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)).$$

Now we have $\mathbb{I}$ finitary iff, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{implies} \quad \phi \in D_\Sigma(\Psi), \text{ some } \Psi \subseteq_f \Phi,$$

iff, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}(\Sigma)$,

$$\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \quad \text{implies} \quad \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Psi)), \text{ some } \Psi \subseteq_f \Phi,$$

which, taking into account the surjectivity of $\langle F, \alpha \rangle$, is equivalent to $\mathbb{I}'$ being finitary. ■

Finally, we show that structurality is also preserved by biological morphisms.

Proposition 1403 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ N^b -algebraic systems, $\mathbb{I} = \langle \mathbf{A}, D \rangle$, $\mathbb{I}' = \langle \mathbf{A}', D' \rangle$ N^b -structures, based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{I} \vdash \mathbb{I}'$ a biological morphism. Then D is structural if and only if D' is structural.*

Proof: Suppose, first, that D is structural. We will use Proposition 1394. Consider $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $T' \in \mathcal{D}'_{F(\Sigma')}$. Then we have

$$D'_{F(\Sigma)}(\text{SEN}'(F(f))^{-1}(T')) = \alpha_{\Sigma}(D_{\Sigma}(\alpha_{\Sigma'}^{-1}(\text{SEN}'(F(f))^{-1}(T'))))$$

(Proposition 1397)

$$\begin{array}{ccc}
 \text{SEN}(\Sigma) & \xrightarrow{\alpha_{\Sigma}} & \text{SEN}'(F(\Sigma)) \\
 \text{SEN}(f) \downarrow & & \downarrow \text{SEN}'(F(f)) \\
 \text{SEN}(\Sigma') & \xrightarrow{\alpha_{\Sigma'}} & \text{SEN}'(F(\Sigma'))
 \end{array}$$

$$\begin{aligned}
 &= \alpha_{\Sigma}(D_{\Sigma}(\text{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T')))) \\
 &\quad \text{(Commutativity of Rectangle)} \\
 &= \alpha_{\Sigma}(\text{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T'))) \\
 &\quad \text{(Propositions 1397 and 1394)} \\
 &= \alpha_{\Sigma}(\alpha_{\Sigma'}^{-1}(\text{SEN}'(F(f))^{-1}(T'))) \\
 &\quad \text{(Commutativity of Rectangle)} \\
 &= \text{SEN}'(F(f))^{-1}(T'). \\
 &\quad \text{(Surjectivity of } \langle F, \alpha \rangle)
 \end{aligned}$$

By Proposition 1394 and taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that D' is structural.

Assume, conversely, that D' is structural. Let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $T \in \mathcal{D}_{\Sigma'}$. Then, there exists, by Proposition 1397, $T' \in \mathcal{D}'_{F(\Sigma')}$, such that $T = \alpha_{\Sigma'}^{-1}(T')$. So we have

$$\begin{aligned}
 D_{\Sigma}(\text{SEN}(f)^{-1}(T)) &= D_{\Sigma}(\text{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T'))) \\
 &= D_{\Sigma}(\alpha_{\Sigma'}^{-1}(\text{SEN}'(F(f))^{-1}(T'))) \\
 &\quad \text{(Commutativity of Rectangle)} \\
 &= \alpha_{\Sigma}^{-1}(\text{SEN}'(F(f))^{-1}(T')) \\
 &\quad \text{(Propositions 1394 and 1397)} \\
 &= \text{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T')) \\
 &\quad \text{(Commutativity of Rectangle)} \\
 &= \text{SEN}(f)^{-1}(T).
 \end{aligned}$$

We conclude, using Proposition 1394, that D is structural. ■

19.2 Quotients and Morphisms

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system and $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an N^b -algebraic system. Given a congruence system $\theta \in \text{ConSys}(\mathbf{A})$,

we may define the quotient $\mathbf{A}^\theta := \mathbf{A}/\theta$ and the quotient morphism $\langle I, \pi^\theta \rangle : \mathbf{A} \rightarrow \mathbf{A}^\theta$. Moreover, given an N^b -structure $\mathbb{L} = \langle \mathbf{A}, D \rangle$, we define on the quotient $\mathbf{A}^\theta$ the closure family $D^\theta : \mathcal{P}\text{SEN}^\theta \rightarrow \mathcal{P}\text{SEN}^\theta$ by stipulating that its corresponding closure family $\mathcal{D}^\theta \subseteq \mathcal{P}\text{SEN}^\theta$ is given by

$$\mathcal{D}^\theta := \{T \in \text{SenFam}(\mathbf{A}^\theta) : (\pi^\theta)^{-1}(T) \in \mathcal{D}\}.$$

It is not difficult to see that $\mathcal{D}^\theta$ is indeed a closure family on $\mathbf{A}^\theta$. Indeed, for all $T^i \in \mathcal{D}^\theta$, $i \in I$, we have

$$(\pi^\theta)^{-1}\left(\bigcap_{i \in I} T^i\right) = \bigcap_{i \in I} (\pi^\theta)^{-1}(T^i) \in \mathcal{D},$$

since $\mathcal{D}$ is, by hypothesis, a closure family on $\mathbf{A}$. The N^b -structure $\mathbb{L}^\theta = \langle \mathbf{A}^\theta, D^\theta \rangle$ is called the **quotient of $\mathbb{L}$ by θ** .

Consider, again, the quotient morphism $\langle I, \pi^\theta \rangle : \mathbf{A} \rightarrow \mathbf{A}^\theta$. It is not difficult to see either that $\langle I, \pi^\theta \rangle : \mathbb{L} \rightarrow \mathbb{L}^\theta$ is a logical morphism. This simply follows from the definition of $\mathbb{L}^\theta$ and the characterization in Proposition 1395. This logical morphism is also termed the **quotient morphism** from $\mathbb{L}$ onto $\mathbb{L}^\theta$.

Suppose, now, that, in addition to being a congruence system on $\mathbf{A}$, θ is a logical congruence system of $\mathbb{L}$, $\theta \in \text{ConSys}(\mathbb{L})$. An equivalent formalization is to say that $\theta \leq \tilde{\Omega}(\mathbb{L})$. This hypothesis ensures that $\mathcal{D}^\theta = \pi^\theta(\mathcal{D})$ and that, moreover, $\text{Ker}(\langle I, \pi^\theta \rangle) = \theta \in \text{ConSys}(\mathbb{L})$. Therefore, by Part (v) of Proposition 1397, the quotient morphism $\langle I, \pi^\theta \rangle : \mathbb{L} \rightarrow \mathbb{L}^\theta$ becomes a bilogical morphism.

Having behind us this short introduction, we proceed to formulate and prove the Morphism Theorems, which correspond for N^b -structures to the Homomorphism, Second Isomorphism and Correspondence Theorems of Universal Algebra in forms reminiscent of the versions applicable in the context of abstract logics of abstract algebraic logic.

Theorem 1404 (Morphism Theorem) *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \text{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \text{Sign}', \text{SEN}', N' \rangle$ two N^b -algebraic systems, and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ two N^b -structures. If $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, with $\theta = \text{Ker}(\langle F, \alpha \rangle)$, then there exists an α -isomorphism $\langle F, \beta \rangle : \mathbb{L}^\theta \vdash \mathbb{L}'$, that makes the following diagram commute*

$$\begin{array}{ccc} \mathbb{L} & \xrightarrow{\langle F, \alpha \rangle} & \mathbb{L}' \\ & \searrow \langle I, \pi^\theta \rangle & \nearrow \langle F, \beta \rangle \\ & \mathbb{L}^\theta & \end{array}$$

Proof: Since $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, we get that $\theta = \text{Ker}(\langle F, \alpha \rangle)$ is a congruence system of $\mathbb{L}$. Thus, $\langle I, \pi^\theta \rangle : \mathbb{L} \vdash \mathbb{L}^\theta$ is also a

biological morphism. Define $\langle F, \beta \rangle : \mathbf{A}^\theta \rightarrow \mathbf{A}'$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\beta_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\phi).$$

First, $\langle F, \beta \rangle$ is well-defined: This is straightforward, since, if $\langle \phi, \psi \rangle \in \theta_\Sigma = \text{Ker}_\Sigma(\langle F, \alpha \rangle)$, then, by definition, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$.

Second, $\beta : \text{SEN}^\theta \rightarrow \text{SEN}' \circ F$ is natural: We have, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\begin{array}{ccc} \text{SEN}^\theta(\Sigma) & \xrightarrow{\beta_\Sigma} & \text{SEN}'(F(\Sigma)) \\ \text{SEN}^\theta(f) \downarrow & & \downarrow \text{SEN}'(F(f)) \\ \text{SEN}^\theta(\Sigma') & \xrightarrow{\beta_{\Sigma'}} & \text{SEN}'(F(\Sigma')) \end{array}$$

$$\begin{aligned} \text{SEN}'(F(f))(\beta_\Sigma(\phi/\theta_\Sigma)) &= \text{SEN}'(F(f))(\alpha_\Sigma(\phi)) \\ &= \alpha_{\Sigma'}(\text{SEN}(f)(\phi)) \\ &= \beta_{\Sigma'}(\text{SEN}(f)(\phi)/\theta_{\Sigma'}) \\ &= \beta_{\Sigma'}(\text{SEN}^\theta(f)(\phi/\theta_\Sigma)). \end{aligned}$$

Third, $\langle F, \beta \rangle : \mathbf{A}^\theta \rightarrow \mathbf{A}'$ is surjective: This is also clear, based on the fact that $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$ is surjective.

Fourth, $\langle F, \beta \rangle : \mathbb{L}^\theta \vdash \mathbb{L}'$ is biological: Since surjectivity was pointed out above, we only have to show Part (iii) of Proposition 1397. First, note that $\text{Ker}(\langle F, \beta \rangle) \in \text{ConSys}(\mathbb{L}^\theta)$, since, for all $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, if $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma \rangle \in \text{Ker}_\Sigma(\langle F, \beta \rangle)$, then $\beta_\Sigma(\phi/\theta_\Sigma) = \beta_\Sigma(\psi/\theta_\Sigma)$, whence $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$. Thus, since $\text{Ker}(\langle F, \alpha \rangle) \in \text{ConSys}(\mathbb{L})$, $D_\Sigma(\phi) = D_\Sigma(\psi)$ and, hence, $D_\Sigma^\theta(\phi/\theta_\Sigma) = D_\Sigma^\theta(\psi/\theta_\Sigma)$. This proves that $\text{Ker}(\langle F, \beta \rangle) \in \text{ConSys}(\mathbb{L}^\theta)$. Finally, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)$,

$$\begin{aligned} \beta_\Sigma(D_\Sigma^\theta(\Phi/\theta_\Sigma)) &= \beta_\Sigma(D_\Sigma(\Phi)/\theta_\Sigma) \\ &= \alpha_\Sigma(D_\Sigma(\Phi)) \\ &= D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \\ &= D'_{F(\Sigma)}(\beta_\Sigma(\Phi/\theta_\Sigma)). \end{aligned}$$

This shows that both conditions in Part (iii) of Proposition 1397 are satisfied and, hence, $\langle F, \beta \rangle : \mathbb{L}^\theta \vdash \mathbb{L}'$ is a biological morphism.

Fifth, for all $\Sigma \in |\mathbf{Sign}|$ $\beta_\Sigma : \text{SEN}^\theta(\Sigma) \rightarrow \text{SEN}'(F(\Sigma))$ is injective. If $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\beta_\Sigma(\phi/\theta_\Sigma) = \beta_\Sigma(\psi/\theta_\Sigma)$, then $\alpha_\Sigma(\phi) = \beta_\Sigma(\phi)$, whence $\phi/\theta_\Sigma = \psi/\theta_\Sigma$. We now conclude that $\langle F, \beta \rangle : \mathbb{L}^\theta \vdash^\alpha \mathbb{L}'$ is an α -isomorphism.

Finally, the triangle commutes: This is clear, since, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, $\beta_\Sigma(\pi_\Sigma^\theta(\phi)) = \beta_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\phi)$. ■

Theorem 1405 (Isomorphism Theorem) *Suppose $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ is a base algebraic system and $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ an N^b -algebraic system. If $\mathbb{I} = \langle \mathbf{A}, D \rangle$ is an N^b -structure and $\theta, \theta' \in \text{ConSys}(\mathbb{I})$, such that $\theta \leq \theta'$, then $\theta'/\theta \in \text{ConSys}(\mathbb{I}^\theta)$ and $(\mathbb{I}^\theta)^{\theta'/\theta} \cong \mathbb{I}^{\theta'}$.*

Proof: First, we show that $\theta'/\theta \in \text{ConSys}(\mathbb{I}^\theta)$. To this end, let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathbf{SEN}(\Sigma)$, such that $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma \rangle \in \theta'_\Sigma/\theta_\Sigma$. Then $\langle \phi, \psi \rangle \in \theta'_\Sigma$, whence, since $\theta' \in \text{ConSys}(\mathbb{I})$, $D_\Sigma(\phi) = D_\Sigma(\psi)$. Hence, $D_\Sigma^\theta(\phi/\theta_\Sigma) = D_\Sigma^\theta(\psi/\theta_\Sigma)$. So $\theta'/\theta \in \text{ConSys}(\mathbb{I}^\theta)$.

To finish the proof, we define $\langle I, \alpha \rangle : \mathbb{I}^\theta \rightarrow \mathbb{I}^{\theta'}$, by setting, for all $\Sigma \in |\mathbf{Sign}|$, $\phi \in \mathbf{SEN}(\Sigma)$,

$$\alpha_\Sigma(\phi/\theta_\Sigma) = \phi/\theta'_\Sigma.$$

If we show that $\langle I, \alpha \rangle : \mathbb{I}^\theta \rightarrow \mathbb{I}^{\theta'}$ is a bilogical morphism, then, by noting that $\text{Ker}(\langle I, \alpha \rangle) = \theta'/\theta$ and applying Theorem 1404,

$$\begin{array}{ccc} \mathbb{I}^\theta & \xrightarrow{\langle I, \alpha \rangle} & \mathbb{I}^{\theta'} \\ & \searrow \langle I, \pi^{\theta'/\theta} \rangle & \nearrow \langle I, \beta \rangle \\ & (\mathbb{I}^\theta)^{\theta'/\theta} & \end{array}$$

we will have the sought after isomorphism $\langle I, \beta \rangle : (\mathbb{I}^\theta)^{\theta'/\theta} \cong \mathbb{I}^{\theta'}$.

First, $\langle I, \alpha \rangle : \mathbf{SEN}^\theta \rightarrow \mathbf{SEN}^{\theta'}$ is well-defined, since, for all $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \mathbf{SEN}(\Sigma)$, if $\langle \phi, \psi \rangle \in \theta_\Sigma$, then, by hypothesis, $\langle \phi, \psi \rangle \in \theta'_\Sigma$, showing that $\alpha_\Sigma(\phi/\theta_\Sigma) = \alpha_\Sigma(\psi/\theta_\Sigma)$.

Second, $\alpha : \mathbf{SEN}^\theta \rightarrow \mathbf{SEN}^{\theta'}$ is natural, since, for all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \mathbf{SEN}(\Sigma)$,

$$\begin{array}{ccc} \mathbf{SEN}^\theta(\Sigma) & \xrightarrow{\alpha_\Sigma} & \mathbf{SEN}^{\theta'}(\Sigma) \\ \mathbf{SEN}^\theta(f) \downarrow & & \downarrow \mathbf{SEN}^{\theta'}(f) \\ \mathbf{SEN}^\theta(\Sigma') & \xrightarrow{\alpha_{\Sigma'}} & \mathbf{SEN}^{\theta'}(\Sigma') \end{array}$$

$$\begin{aligned} \mathbf{SEN}^{\theta'}(f)(\alpha_\Sigma(\phi/\theta_\Sigma)) &= \mathbf{SEN}^{\theta'}(f)(\phi/\theta'_\Sigma) \\ &= \mathbf{SEN}(f)(\phi)/\theta'_{\Sigma'} \\ &= \alpha_{\Sigma'}(\mathbf{SEN}(f)(\phi)/\theta_{\Sigma'}) \\ &= \alpha_{\Sigma'}(\mathbf{SEN}^\theta(\phi/\theta_\Sigma)). \end{aligned}$$

Third, it is clear that $\langle I, \alpha \rangle : \mathbf{A}^\theta \rightarrow \mathbf{A}^{\theta'}$ is surjective. So it suffices now to show that the conditions in Part (iii) of Proposition 1397 are satisfied.

First, $\text{Ker}(\langle I, \alpha \rangle) = \theta'/\theta \in \text{ConSys}(\mathbb{L}^\theta)$, as was shown above. Finally, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)$, we have

$$\begin{aligned} \alpha_\Sigma(D_\Sigma^\theta(\Phi/\theta_\Sigma)) &= \alpha_\Sigma(D_\Sigma(\Phi)/\theta_\Sigma) \\ &= D_\Sigma(\Phi)/\theta'_\Sigma \\ &= D_\Sigma^{\theta'}(\Phi/\theta'_\Sigma) \\ &= D_\Sigma^{\theta'}(\alpha_\Sigma(\Phi/\theta_\Sigma)). \end{aligned}$$

Therefore, $\langle I, \alpha \rangle : \mathbb{L}^\theta \mapsto \mathbb{L}^{\theta'}$ is indeed a bilogical morphism. $\blacksquare$

Theorem 1406 (Correspondence Theorem) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ an N^b -algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ an N^b -structure and $\theta \in \text{ConSys}(\mathbb{L})$. Then $\theta' \mapsto \theta'/\theta$ defines an order isomorphism between the principal filter $[\theta, \tilde{\Omega}(\mathbb{L})]$ in $\mathbf{ConSys}(\mathbb{L})$ and the complete lattice $\mathbf{ConSys}(\mathbb{L}^\theta)$.*

Proof: By Theorem 1405, the mapping $\theta' \mapsto \theta'/\theta$ is a well defined mapping from $[\theta, \tilde{\Omega}(\mathbb{L})]$ into $\text{ConSys}(\mathbb{L}^\theta)$. The mapping is also one-to-one. To see this, assume $\theta'/\theta = \theta''/\theta$ and let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta'_\Sigma$. Then $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma \rangle \in \theta'_\Sigma/\theta_\Sigma = \theta''_\Sigma/\theta_\Sigma$ and, therefore, $\langle \phi, \psi \rangle \in \theta''_\Sigma$. Thus, $\theta' \leq \theta''$ and, hence, by symmetry, $\theta' = \theta''$. The mapping is also surjective. To prove surjectivity, Let $\eta \in \text{ConSys}(\mathbb{L}^\theta)$. Define $\theta' = \{\theta'_\Sigma\}_{\Sigma \in |\mathbf{Sign}|}$ by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\theta'_\Sigma = \{ \langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : \langle \phi/\theta_\Sigma, \psi/\theta_\Sigma \rangle \in \eta_\Sigma \}.$$

It is easy to see that θ' is a congruence system on $\mathbf{A}$. It is also easy to see that $\theta \leq \theta'$. Furthermore, θ' is a congruence system of $\mathbb{L}$, since, if $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta'_\Sigma$, we get $\langle \phi/\theta_\Sigma, \psi/\theta_\Sigma \rangle \in \eta_\Sigma \in \text{ConSys}(\mathbb{L}^\theta)$, whence $D_\Sigma^\theta(\phi/\theta_\Sigma) = D_\Sigma^\theta(\psi/\theta_\Sigma)$, i.e., $D_\Sigma(\phi)/\theta_\Sigma = D_\Sigma(\psi)/\theta_\Sigma$ and, since $\theta \in \text{ConSys}(\mathbb{L})$, $D_\Sigma(\phi) = D_\Sigma(\psi)$. Since $\theta' \mapsto \theta'/\theta = \eta$, it follows that the mapping is also surjective. Finally, it is obvious that both it and its inverse are monotone, which establishes that it is an order isomorphism. $\blacksquare$

The Correspondence Theorem implies immediately a relation between the quotient of a Tarski congruence system and the Tarski system of the corresponding quotient structure.

Corollary 1407 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ an N^b -algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ an N^b -structure and $\theta \in \text{ConSys}(\mathbb{L})$. Then*

$$\tilde{\Omega}(\mathbb{L}^\theta) = \tilde{\Omega}(\mathbb{L})/\theta.$$

Proof: We take $\theta' = \tilde{\Omega}(\mathbb{L})$ and apply the Correspondence Theorem 1406. $\blacksquare$

Corollary 1407 allows us also to conclude that the quotient of any N^b -structure by its Tarski congruence system has an identity Tarski congruence system. More precisely,

$$\widetilde{\Omega}(\mathbb{I}^{\widetilde{\Omega}(\mathbb{I})}) = \widetilde{\Omega}(\mathbb{I})/\widetilde{\Omega}(\mathbb{I}) = \Delta^{\mathbf{A}/\widetilde{\Omega}(\mathbb{I})}.$$

This leads to the definition of a reduced N^b -structure and of the reduction of an N^b -structure.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ an N^b -algebraic system and $\mathbb{I} = \langle \mathbf{A}, D \rangle$ an N^b -structure. We call $\mathbb{I}$ **reduced** if $\widetilde{\Omega}(\mathbb{I}) = \Delta^{\mathbf{A}}$. More generally, we set $\mathbb{I}^* = \mathbb{I}^{\widetilde{\Omega}(\mathbb{I})}$ and call $\mathbb{I}^*$ the **reduction** of $\mathbb{I}$. Moreover, for a class $\mathbf{L}$ of N^b -structures, we set

$$\mathbf{L}^* = \{\mathbb{I}^* : \mathbb{I} \in \mathbf{L}\}.$$

By the comments following Corollary 1407, $\mathbb{I}^*$ is reduced for any N^b -structure $\mathbb{I}$. In case $\mathbb{I}$ is reduced to start with, then $\mathbb{I}^* \cong \mathbb{I}$ and, in this case, $\mathbb{I}^*$ will be identified with $\mathbb{I}$.

Another important consequence of the Correspondence Theorem is that reducing a quotient of a structure results in a reduced structure that is isomorphic (and, thus, can be identified) with the reduction of the originally given structure.

Proposition 1408 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ an N^b -algebraic system, $\mathbb{I} = \langle \mathbf{A}, D \rangle$ an N^b -structure and $\theta \in \text{ConSys}(\mathbb{I})$. Then*

$$(\mathbb{I}^\theta)^* \cong \mathbb{I}^*.$$

Proof: We have

$$\begin{aligned} (\mathbb{I}^\theta)^* &= (\mathbb{I}^\theta)^{\widetilde{\Omega}(\mathbb{I}^\theta)} \quad (\text{Definition of Reduction}) \\ &= (\mathbb{I}^\theta)^{\widetilde{\Omega}(\mathbb{I})/\theta} \quad (\text{Corollary 1407}) \\ &\cong \mathbb{I}^{\widetilde{\Omega}(\mathbb{I})} \quad (\text{Theorem 1405}) \\ &= \mathbb{I}^*. \quad (\text{Definition of Reduction}) \end{aligned}$$

■

Generalizing Proposition 1408, we can show that a similar relation holds between the reductions of two N^b -structures that are related via a biological morphism.

Proposition 1409 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ N^b -algebraic systems and $\mathbb{I} = \langle \mathbf{A}, D \rangle$ and $\mathbb{I}' = \langle \mathbf{A}', D' \rangle$ N^b -structures, based on $\mathbf{A}$ and $\mathbf{A}'$, respectively. If there exists a biological morphism $\langle F, \alpha \rangle : \mathbb{I} \vdash \mathbb{I}'$, then there exists an α -isomorphism*

$$\mathbb{I}^* \vdash^\alpha \mathbb{I}'^*.$$

Proof: We define $\langle F, \beta \rangle : \mathbf{A}^* \rightarrow \mathbf{A}'^*$ by setting, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\beta_\Sigma(\phi / \tilde{\Omega}_\Sigma(\mathbb{I})) = \alpha_\Sigma(\phi) / \tilde{\Omega}_{F(\Sigma)}(\mathbb{I}'),$$

i.e., $\langle F, \beta \rangle$ is the morphism that makes the following rectangle commute

$$\begin{array}{ccc} \mathbf{A} & \xrightarrow{\langle F, \alpha \rangle} & \mathbf{A}' \\ \langle I, \pi^{\tilde{\Omega}(\mathbb{I})} \rangle \downarrow & & \downarrow \langle I, \pi^{\tilde{\Omega}(\mathbb{I}')} \rangle \\ \mathbf{A}^* & \xrightarrow{\langle F, \beta \rangle} & \mathbf{A}'^* \end{array}$$

First, $\langle I, \beta \rangle$ is well-defined: In fact, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \tilde{\Omega}_\Sigma(\mathbb{I})$, then, since, by Corollary 1401, $\Omega(\mathbb{I}) = \alpha^{-1}(\tilde{\Omega}(\mathbb{I}'))$, we get that $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \tilde{\Omega}_{F(\Sigma)}(\mathbb{I}')$.

Second $\beta : \text{SEN}^{\tilde{\Omega}(\mathbb{I})} \rightarrow \text{SEN}^{\tilde{\Omega}(\mathbb{I}')} \circ F$ is a natural transformation: Let $\Sigma, \Sigma' \in |\mathbf{Sign}|$, $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and $\phi \in \text{SEN}(\Sigma)$. We have

$$\begin{array}{ccc} \text{SEN}^{\tilde{\Omega}(\mathbb{I})}(\Sigma) & \xrightarrow{\beta_\Sigma} & \text{SEN}^{\tilde{\Omega}(\mathbb{I}')}(\Sigma) \\ \text{SEN}^{\tilde{\Omega}(\mathbb{I})}(f) \downarrow & & \downarrow \text{SEN}^{\tilde{\Omega}(\mathbb{I}')}(\Sigma') \\ \text{SEN}^{\tilde{\Omega}(\mathbb{I})}(\Sigma') & \xrightarrow{\beta_{\Sigma'}} & \text{SEN}^{\tilde{\Omega}(\mathbb{I}')}(\Sigma') \end{array}$$

$$\begin{aligned} & \text{SEN}^{\tilde{\Omega}(\mathbb{I}')}(\Sigma')(f)(\beta_\Sigma(\phi / \tilde{\Omega}_\Sigma(\mathbb{I}))) \\ &= \text{SEN}^{\tilde{\Omega}(\mathbb{I}')}(\Sigma')(f)(\alpha_\Sigma(\phi) / \tilde{\Omega}_{F(\Sigma)}(\mathbb{I}')) \\ &= \text{SEN}'(\Sigma')(f)(\alpha_\Sigma(\phi) / \tilde{\Omega}_{F(\Sigma')}(\mathbb{I}')) \\ &= \alpha_{\Sigma'}(\text{SEN}(f)(\phi)) / \tilde{\Omega}_{F(\Sigma')}(\mathbb{I}') \\ &= \beta_{\Sigma'}(\text{SEN}(f)(\phi) / \tilde{\Omega}_{\Sigma'}(\mathbb{I})) \\ &= \beta_{\Sigma'}(\text{SEN}^{\tilde{\Omega}(\mathbb{I})}(f)(\phi / \tilde{\Omega}_\Sigma(\mathbb{I}))). \end{aligned}$$

Third, for every $\Sigma \in |\mathbf{Sign}|$, $\beta_\Sigma : \text{SEN}^{\tilde{\Omega}(\mathbb{I})}(\Sigma) \rightarrow \text{SEN}^{\tilde{\Omega}(\mathbb{I}')}(\Sigma)$ is a bijection. Surjectivity is immediate and follows from the fact that both $\langle F, \alpha \rangle$ and $\langle I, \pi^{\tilde{\Omega}(\mathbb{I}')} \rangle$ are surjective. For injectivity, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\beta_\Sigma(\phi / \tilde{\Omega}_\Sigma(\mathbb{I})) = \beta_\Sigma(\psi / \tilde{\Omega}_\Sigma(\mathbb{I}))$, then $\alpha_\Sigma(\phi) / \tilde{\Omega}_{F(\Sigma)}(\mathbb{I}') = \alpha_\Sigma(\psi) / \tilde{\Omega}_{F(\Sigma)}(\mathbb{I}')$, whence

$$\langle \phi, \psi \rangle \in \alpha_\Sigma^{-1}(\tilde{\Omega}_{F(\Sigma)}(\mathbb{I}')) = \tilde{\Omega}_\Sigma(\mathbb{I}).$$

This proves that β_Σ is indeed a bijection.

Finally, we use Part (iii) of Proposition 1397 to show that it is a biological morphism. Of course, since $\langle F, \beta \rangle$ has injective components, we get

$\text{Ker}(\langle F, \beta \rangle) = \Delta^{\mathbf{A}^*}$ and, hence it is a congruence system of $\mathbb{L}^*$. Finally, if $\Sigma \in |\mathbf{Sign}|$ and $\Phi \subseteq \text{SEN}(\Sigma)$, we have

$$\begin{aligned} \beta_\Sigma(D_\Sigma^*(\Phi/\tilde{\Omega}_\Sigma(\mathbb{L}))) &= \beta_\Sigma(D_\Sigma(\Phi)/\tilde{\Omega}_\Sigma(\mathbb{L})) \\ &= \alpha_\Sigma(D_\Sigma(\Phi))/\tilde{\Omega}_{F(\Sigma)}(\mathbb{L}') \\ &= D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))/\tilde{\Omega}_{F(\Sigma)}(\mathbb{L}') \\ &= D_{F(\Sigma)}^*(\alpha_\Sigma(\Phi)/\tilde{\Omega}_{F(\Sigma)}(\mathbb{L}')) \\ &= D_{F(\Sigma)}^*(\beta_\Sigma(\Phi/\tilde{\Omega}_\Sigma(\mathbb{L}))). \end{aligned}$$

Thus, $\langle F, \beta \rangle : \mathbb{L}^* \vdash^\alpha \mathbb{L}'^*$ is an α -isomorphism, as claimed. $\blacksquare$

In case $\mathbf{Sign}' = \mathbf{Sign}$ and $\langle I, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a biological morphism, with $I : \mathbf{Sign} \rightarrow \mathbf{Sign}$ the identity functor, then we obtain

Corollary 1410 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ and $\mathbf{A}' = \langle \mathbf{Sign}, \text{SEN}', N' \rangle$ N^b -algebraic systems and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ N^b -structures, based on $\mathbf{A}$ and $\mathbf{A}'$, respectively. If there exists a biological morphism $\langle I, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$, then*

$$\mathbb{L}^* \cong \mathbb{L}'^*.$$

Proof: Immediate by Proposition 1409. $\blacksquare$

The next result is a “fill-in” lemma that provides sufficient conditions under which one can find a morphism that “fills-in” the third side of a commutative triangle, given arrows emanating from one of its vertices.

Proposition 1411 (Fill-In Lemma) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ and $\mathbf{A}'' = \langle \mathbf{Sign}, \text{SEN}'', N'' \rangle$ N^b -algebraic systems and $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ and $\mathbb{L}'' = \langle \mathbf{A}'', D'' \rangle$ N^b -structures, based on $\mathbf{A}$, $\mathbf{A}'$ and $\mathbf{A}''$, respectively. Given a logical morphism $\langle F, \alpha \rangle : \mathbb{L} \dashv \mathbb{L}'$ and a biological morphism $\langle I, \beta \rangle : \mathbb{L} \vdash \mathbb{L}''$, such that $\ker(\langle I, \beta \rangle) \leq \text{Ker}(\langle F, \alpha \rangle)$,*

$$\begin{array}{ccc} \mathbb{L} & \xrightarrow{\langle F, \alpha \rangle} & \mathbb{L}' \\ & \searrow \langle I, \beta \rangle & \nearrow \langle F, \gamma \rangle \\ & \mathbb{L}'' & \end{array}$$

there exists a unique logical morphism $\langle F, \gamma \rangle : \mathbb{L}'' \dashv \mathbb{L}'$, such that the triangle commutes. Moreover, $\langle F, \gamma \rangle$ is biological if and only if $\langle F, \alpha \rangle$ is biological.

Proof: Define, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}''(\Sigma)$,

$$\gamma_\Sigma(\phi) = \alpha_\Sigma(\psi),$$

where $\psi \in \text{SEN}(\Sigma)$, such that $\beta_\Sigma(\psi) = \phi$.

First, since, for all $\Sigma \in |\mathbf{Sign}|$, $\psi, \psi' \in \text{SEN}(\Sigma)$, such that $\beta_\Sigma(\psi) = \beta_\Sigma(\psi')$, we have, by hypothesis, $\alpha_\Sigma(\psi) = \alpha_\Sigma(\psi')$, this definition is sound.

Second, $\gamma : \text{SEN}'' \rightarrow \text{SEN}' \circ F$ is a natural transformation: For all $\Sigma, \Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\phi \in \text{SEN}''(\Sigma)$, such that $\phi = \beta_\Sigma(\psi)$, for some $\psi \in \text{SEN}(\Sigma)$, we have

$$\begin{array}{ccc}
 \text{SEN}''(\Sigma) & \xrightarrow{\gamma_\Sigma} & \text{SEN}'(F(\Sigma)) \\
 \text{SEN}''(f) \downarrow & & \downarrow \text{SEN}'(F(f)) \\
 \text{SEN}''(\Sigma') & \xrightarrow{\gamma_{\Sigma'}} & \text{SEN}'(F(\Sigma'))
 \end{array}$$

$$\begin{aligned}
 \text{SEN}'(F(f))(\gamma_\Sigma(\phi)) &= \text{SEN}'(F(f))(\alpha_\Sigma(\psi)) \\
 &= \alpha_{\Sigma'}(\text{SEN}(f)(\psi)) \\
 &= \gamma_{\Sigma'}(\text{SEN}''(f)(\phi)),
 \end{aligned}$$

where the last equality follows from

$$\beta_{\Sigma'}(\text{SEN}(f)(\psi)) = \text{SEN}''(f)(\beta_\Sigma(\psi)) = \text{SEN}''(f)(\phi)$$

and the definition of $\gamma_{\Sigma'}$.

Now it is clear that the triangle of the diagram commutes. Moreover, for all $T' \in \text{ThFam}(\mathbb{I}\mathbb{L}')$, since $\langle F, \alpha \rangle$ is a logical morphism, $\alpha^{-1}(T') \in \text{ThFam}(\mathbb{I}\mathbb{L})$ and, hence, by commutativity, $\beta^{-1}(\gamma^{-1}(T')) \in \text{ThFam}(\mathbb{I}\mathbb{L})$. Hence, since $\langle I, \beta \rangle$ is a biological morphism, $\gamma^{-1}(T') \in \text{ThFam}(\mathbb{I}\mathbb{L}'')$. This proves that $\langle F, \gamma \rangle$ is also a logical morphism.

Finally, for the last statement, note that $\langle F, \gamma \rangle$ is surjective if and only if $\langle F, \alpha \rangle$ is surjective, and, furthermore, $\text{ThFam}(\mathbb{I}\mathbb{L}'') = \gamma^{-1}(\text{ThFam}(\mathbb{I}\mathbb{L}'))$ if and only if $\beta^{-1}(\text{ThFam}(\mathbb{I}\mathbb{L}'')) = \alpha^{-1}(\text{ThFam}(\mathbb{I}\mathbb{L}'))$ if and only if $\text{ThFam}(\mathbb{I}\mathbb{L}) = \alpha^{-1}(\text{ThFam}(\mathbb{I}\mathbb{L}'))$. We conclude, taking into account Part (vi) of Proposition 1397, that $\langle F, \gamma \rangle$ is biological if and only if $\langle F, \alpha \rangle$ is. ■

19.3 Filter Families and π -Structures

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ an $\mathbf{F}$ -algebraic system. We have seen that the collection $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$ of $\mathcal{I}$ -filter families on $\mathcal{A}$ forms a complete lattice $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) = \langle \text{FiFam}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ under signature-wise inclusion. Therefore, the pair $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ constitutes an $\mathbf{F}$ -structure. This $\mathbf{F}$ -structure will also be denoted interchangeably by $\langle \mathcal{A}, C^{\mathcal{I}, \mathcal{A}} \rangle$ or $\langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle$, with reference to the closure (operator) family or the

closed set family corresponding to $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Such pairs will play an important role in this chapter, since they will be used as models of $\mathcal{I}$ that provide a semantics for the logical system formalized by $\mathcal{I}$.

It is clear that the closure families of $\mathbf{F}$ -structures of this form are structural and, hence, $\mathbf{F}$ -structures of this form are actually π -institutions.

Proposition 1412 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system. Then $C^{\mathcal{I}, \mathcal{A}} : \mathcal{P}\text{SEN} \rightarrow \mathcal{P}\text{SEN}$ is a structural closure operator on SEN .*

Proof: We use Proposition 1394. Let $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, $T \in \mathcal{C}_{F(\Sigma')}^{\mathcal{I}, \mathcal{A}}$. Then, by Lemma 51, $\alpha_{\Sigma'}^{-1}(T) \in \mathcal{C}_{\Sigma'}$. Since C is structural, by Proposition 1394, $\text{SEN}(f)^{-1}(\alpha_{\Sigma'}^{-1}(T)) \in \mathcal{C}_{\Sigma}$. By the naturality of $\alpha : \text{SEN}^b \rightarrow \text{SEN} \circ F$, we get $\alpha_{\Sigma}^{-1}(\text{SEN}(F(f))^{-1}(T)) \in \mathcal{C}_{\Sigma}$, whence, again by Lemma 51, $\text{SEN}(F(f))^{-1}(T) \in \mathcal{C}_{\Sigma}^{\mathcal{I}, \mathcal{A}}$. Using the surjectivity of $\langle F, \alpha \rangle$ and Proposition 1394, we conclude that $C^{\mathcal{I}, \mathcal{A}}$ is structural. ■

Our next result characterizes biological morphisms between $\mathbf{F}$ -structures of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.

Proposition 1413 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ $\mathbf{F}$ -algebraic systems, such that, there exists a surjective $\langle G, \gamma \rangle : \mathbf{A} \rightarrow \mathbf{A}'$, such that*

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\ \mathbf{A} & \xrightarrow{\langle G, \gamma \rangle} & \mathbf{A}' \end{array}$$

$\langle G, \gamma \rangle \circ \langle F, \alpha \rangle = \langle F', \alpha' \rangle$. Then the following statements are equivalent:

- (i) $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle \vdash \langle \mathcal{A}', \mathcal{C}^{\mathcal{I}, \mathcal{A}'} \rangle$ is a biological morphism;
- (ii) For every $\Sigma \in |\mathbf{Sign}|$, $\gamma_{\Sigma} : \mathcal{C}_{\Sigma}^{\mathcal{I}, \mathcal{A}} \rightarrow \mathcal{C}_{G(\Sigma)}^{\mathcal{I}, \mathcal{A}'}$ is an order isomorphism;
- (iii) For every $\Sigma \in |\mathbf{Sign}|$, and all $T \in \mathcal{C}_{\Sigma}^{\mathcal{I}, \mathcal{A}}$, $\gamma_{\Sigma}(T) \in \mathcal{C}_{G(\Sigma)}^{\mathcal{I}, \mathcal{A}'}$ and, in addition, we have $\text{Ker}(\langle G, \gamma \rangle) \in \text{ConSys}(\langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle)$.

Proof:

(i) $\Rightarrow$ (ii) This is a special case of Proposition 1398.

- (ii) $\Rightarrow$ (iii) The first assertion is obvious. For the second, if $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\gamma_\Sigma(\phi) = \gamma_\Sigma(\psi)$, then, for every $T' \in \text{ThFam}^\mathcal{I}(\mathcal{A}')$,

$$\gamma_\Sigma(\phi) \in T'_{G(\Sigma)} \quad \text{iff} \quad \gamma_\Sigma(\psi) \in T'_{G(\Sigma)}.$$

Hence, for every $T' \in \text{ThFam}^\mathcal{I}(\mathcal{A}')$,

$$\phi \in \gamma_\Sigma^{-1}(T'_{G(\Sigma)}) \quad \text{iff} \quad \psi \in \gamma_\Sigma^{-1}(T'_{G(\Sigma)}).$$

Therefore, by hypothesis, for all $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$,

$$\phi \in T_\Sigma \quad \text{iff} \quad \psi \in T_\Sigma.$$

It now follows that $\text{Ker}(\langle I, \gamma \rangle) \in \text{ConSys}(\langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle)$.

- (iii) $\Rightarrow$ (i) By hypothesis, we get $\gamma(\mathcal{C}_\Sigma^{\mathcal{I}, \mathcal{A}}) \subseteq \mathcal{C}_{G(\Sigma)}^{\mathcal{I}, \mathcal{A}'}$ and also that $\text{Ker}(\langle I, \gamma \rangle) \in \text{ConSys}(\langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle)$. Therefore, by Part (v) of Proposition 1397, it suffices to show that $\mathcal{C}_{G(\Sigma)}^{\mathcal{I}, \mathcal{A}'} \subseteq \gamma(\mathcal{C}_\Sigma^{\mathcal{I}, \mathcal{A}})$. But this follows from the fact that, if $T' \in \mathcal{C}_{G(\Sigma)}^{\mathcal{I}, \mathcal{A}'}$, then by Corollary 55, $\gamma_\Sigma^{-1}(T') \in \mathcal{C}_\Sigma^{\mathcal{I}, \mathcal{A}}$ and, then, by surjectivity, $T' = \gamma_\Sigma(\gamma_\Sigma^{-1}(T'))$. ■

We also have the following related result that, roughly speaking, forces the closure family of a structure that is the biological morphism image of a structure whose closure family consists of all filter families to also consist of the entirely of filter families.

Proposition 1414 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ $\mathbf{F}$ -algebraic systems, such that, there exists a surjective $\langle G, \gamma \rangle : \mathbf{A} \rightarrow \mathbf{A}'$, such that*

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\ \mathbf{A} & \xrightarrow{\langle G, \gamma \rangle} & \mathbf{A}' \end{array}$$

$\langle G, \gamma \rangle \circ \langle F, \alpha \rangle = \langle F', \alpha' \rangle$. If $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle \mapsto \langle \mathcal{A}', \mathcal{C}' \rangle$ is a biological morphism, then $\mathcal{C}' = \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$.

Proof: First, since $\langle G, \gamma \rangle$ is a biological morphism, for all $T' \in \mathcal{C}'$, we have $\gamma^{-1}(T') \in \mathcal{C}^{\mathcal{I}, \mathcal{A}}$. Thus, by Corollary 55, $T' \in \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$. This proves that $\mathcal{C}' \subseteq \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$. Suppose, conversely, that $T' \in \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$. Then, again by Corollary 55, $\gamma^{-1}(T') \in \mathcal{C}^{\mathcal{I}, \mathcal{A}}$. Therefore, since $\langle G, \gamma \rangle$ is a biological morphism, $T' = \gamma(\gamma^{-1}(T')) \in \mathcal{C}'$. We conclude that $\mathcal{C}' = \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$. ■

This result has the following immediate corollaries, one addressing reductions and the other isomorphisms.

Corollary 1415 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system. Then $(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}))^* = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.*

Proof: Let $\mathbb{L} = \langle \mathcal{A}, \mathcal{C}^{\mathcal{I}, \mathcal{A}} \rangle$ and apply Proposition 1414 to the special configuration of morphisms depicted in the diagram:

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F, \pi^{\tilde{\Omega}(\mathbb{L})} \circ \alpha \rangle \\
 \mathbf{A} & \xrightarrow{\langle I, \pi^{\tilde{\Omega}(\mathbb{L})} \rangle} & \mathbf{A}^*
 \end{array}$$

■

Corollary 1416 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ $\mathbf{F}$ -algebraic systems, such that, there exists an isomorphism $\langle G, \gamma \rangle : \mathbf{A} \cong \mathbf{A}'$, such that*

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\
 \mathbf{A} & \xrightarrow{\langle G, \gamma \rangle} & \mathbf{A}'
 \end{array}$$

$\langle G, \gamma \rangle \circ \langle F, \alpha \rangle = \langle F', \alpha' \rangle$. If $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{D} \rangle \vdash \langle \mathcal{A}', \mathcal{D}' \rangle$ is a biological morphism, then $\mathcal{D} = \mathcal{C}^{\mathcal{I}, \mathcal{A}}$ if and only if $\mathcal{D}' = \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$.

Proof: We apply Proposition 1414 twice; once using $\langle G, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$ and once using $\langle G, \gamma \rangle^{-1} : \mathcal{A}' \rightarrow \mathcal{A}$. ■

Corollary 1416 can be strengthened slightly but, to accomplish this, we need the following proposition, which is a sort of symmetric to Proposition 1414.

Proposition 1417 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ two $\mathbf{F}$ -algebraic systems.*

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\
 \mathbf{A} & \xrightarrow{\langle G, \gamma \rangle} & \mathbf{A}'
 \end{array}$$

If $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{D} \rangle \vdash^\alpha \langle \mathcal{A}', \mathcal{C}^{\mathcal{I}, \mathcal{A}'} \rangle$ is an α -isomorphism, then $\mathcal{D} = \mathcal{C}^{\mathcal{I}, \mathcal{A}}$.

Proof: We show, first, that $\mathcal{D} \subseteq \mathcal{C}^{\mathcal{I}, \mathcal{A}}$. Suppose $T \in \mathcal{D}$. Then, since $\langle G, \gamma \rangle$ is an α -isomorphism, there exists, by Proposition 1397, $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}')$, such that $T = \gamma^{-1}(T')$. Now, by Corollary 55, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Hence, $\mathcal{D} \subseteq \mathcal{C}^{\mathcal{I}, \mathcal{A}}$.

Suppose, conversely, that $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\langle G, \gamma \rangle$ is an α -isomorphism, there exists a unique $T' \in \text{SenFam}(\mathcal{A}')$, such that $T = \gamma^{-1}(T')$. Thus, we have

$$\alpha'^{-1}(T') = \alpha^{-1}(\gamma^{-1}(T')) = \alpha^{-1}(T) \in \text{ThFam}(\mathcal{I}).$$

Hence, $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}')$ and, since $\langle G, \gamma \rangle$ is a biological morphism, $T = \gamma^{-1}(T') \in \mathcal{D}$. We conclude that $\mathcal{C}^{\mathcal{I}, \mathcal{A}} \subseteq \mathcal{D}$ and equality follows. ■

A generalization of Corollary 1416 relaxes the requirement that there exists an isomorphism between $\mathbf{F}$ -algebraic systems to the requirement that there exists an α -isomorphism.

Corollary 1418 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ $\mathbf{F}$ -algebraic systems, such that, there exists a surjective morphism $\langle G, \gamma \rangle : \mathbf{A} \cong \mathbf{A}'$, such that*

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\ \mathbf{A} & \xrightarrow{\langle G, \gamma \rangle} & \mathbf{A}' \end{array}$$

$\langle G, \gamma \rangle \circ \langle F, \alpha \rangle = \langle F', \alpha' \rangle$. If $\langle G, \gamma \rangle : \langle \mathcal{A}, \mathcal{D} \rangle \vdash^\alpha \langle \mathcal{A}', \mathcal{D}' \rangle$ is an α -isomorphism, then $\mathcal{D} = \mathcal{C}^{\mathcal{I}, \mathcal{A}}$ if and only if $\mathcal{D}' = \mathcal{C}^{\mathcal{I}, \mathcal{A}'}$.

Proof: We put together Proposition 1414 and Proposition 1417. ■

19.4 $\mathcal{I}$ -Structures

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. Define $C^{\mathbb{L}} = \{C_\Sigma^{\mathbb{L}}\}_{\Sigma \in |\mathbf{Sign}^b|}$ by letting, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$C_\Sigma^{\mathbb{L}} : \mathcal{P}\text{SEN}^b \rightarrow \mathcal{P}\text{SEN}^b$$

be defined, for all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in C_\Sigma^{\mathbb{L}}(\Phi) \quad \text{iff} \quad \text{for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma'), \\ \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) \subseteq D_{F(\Sigma')}(\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi))).$$

More generally, given a class $\mathbf{L}$ of $\mathbf{F}$ -structures, we set

$$C^{\mathbf{L}} = \bigcap \{C^{\mathbb{L}} : \mathbb{L} \in \mathbf{L}\}.$$

We show that $C^{\mathbf{L}}$ is a closure system on $\mathbf{F}$ and, as a result, $\mathcal{I}^{\mathbf{L}} = \langle \mathbf{F}, C^{\mathbf{L}} \rangle$ qualifies as a π -institution.

Proposition 1419 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathbf{L}$ a class of $\mathbf{F}$ -structures. The collection $C^{\mathbf{L}} : \mathcal{P}\mathbf{SEN}^b \rightarrow \mathcal{P}\mathbf{SEN}^b$ is a closure system on $\mathbf{F}$.*

Proof: Inflationarity, monotonicity and idempotency of $C^{\mathbf{L}}$ follow immediately from the corresponding properties of each of the operators of the $\mathbf{F}$ -structures in $\mathbf{L}$. We show structurality in more detail. Suppose $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$, such that $\phi \in C_{\Sigma}^{\mathbf{L}}(\Phi)$. Then, for all $\langle \mathcal{A}, D \rangle \in \mathbf{L}$, all $\Sigma'' \in |\mathbf{Sign}^b|$ and all $g \in \mathbf{Sign}^b(\Sigma, \Sigma'')$,

$$\alpha_{\Sigma''}(\mathbf{SEN}^b(g)(\phi)) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathbf{SEN}^b(g)(\Phi))).$$

Thus, for all $\langle \mathcal{A}, D \rangle \in \mathbf{L}$, all $\Sigma'' \in |\mathbf{Sign}^b|$ and all $h \in \mathbf{Sign}^b(\Sigma', \Sigma'')$,

$$\alpha_{\Sigma''}(\mathbf{SEN}^b(h)(\mathbf{SEN}^b(f)(\phi))) \in D_{F(\Sigma'')}(\alpha_{\Sigma''}(\mathbf{SEN}^b(h)(\mathbf{SEN}^b(f)(\Phi)))).$$

This proves that $\mathbf{SEN}^b(f)(\phi) \in C_{\Sigma'}^{\mathbf{L}}(\mathbf{SEN}^b(f)(\Phi))$, and, hence, that $C^{\mathbf{L}}$ is structural. $\blacksquare$

$C^{\mathbf{L}}$ is termed the **closure system on $\mathbf{F}$ generated by $\mathbf{L}$** and we denote by $\mathcal{I}^{\mathbf{L}} = \langle \mathbf{F}, C^{\mathbf{L}} \rangle$ the π -institution corresponding to $C^{\mathbf{L}}$.

Next, it is shown that $\mathbf{F}$ -structures related by biological morphism generate identical closure systems.

Proposition 1420 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ two $\mathbf{F}$ -algebraic systems, $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ two $\mathbf{F}$ -structures and $\langle G, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism, such that $\langle F', \alpha' \rangle = \langle G, \gamma \rangle \circ \langle F, \alpha \rangle$. Then $C^{\mathbb{L}} = C^{\mathbb{L}'}$.*

Proof: We have, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} \phi \in C_{\Sigma}^{\mathbb{L}}(\Phi) & \text{ iff } \text{for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma') \\ & \quad \alpha_{\Sigma'}(\mathbf{SEN}^b(f)(\phi)) \subseteq D_{F(\Sigma')}(\alpha_{\Sigma'}(\mathbf{SEN}^b(f)(\Phi))) \\ & \text{ iff } \text{for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma') \\ & \quad \gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathbf{SEN}^b(f)(\phi))) \\ & \quad \subseteq D'_{G(F(\Sigma'))}(\gamma_{F(\Sigma')}(\alpha_{\Sigma'}(\mathbf{SEN}^b(f)(\Phi)))) \\ & \text{ iff } \text{for all } \Sigma' \in |\mathbf{Sign}^b|, f \in \mathbf{Sign}^b(\Sigma, \Sigma') \\ & \quad \alpha'_{\Sigma'}(\mathbf{SEN}^b(f)(\phi)) \subseteq D'_{F'(\Sigma')}(\alpha'_{\Sigma'}(\mathbf{SEN}^b(f)(\Phi))) \\ & \text{ iff } \phi \in C_{\Sigma}^{\mathbb{L}'}(\Phi). \end{aligned}$$

We conclude that $C^{\mathbb{L}} = C^{\mathbb{L}'}$. $\blacksquare$

As a special case of Proposition 1420, we get that both an $\mathbf{F}$ -structure and its reduction generate the same closure system on the base algebraic system $\mathbf{F}$.

Corollary 1421 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{I}\mathbf{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. Then $C^{\mathbb{I}\mathbf{L}} = C^{\mathbb{I}\mathbf{L}^*}$.*

Proof: This is obtained directly by Proposition 1420 once we recall that, since $\tilde{\Omega}(\mathbb{I}\mathbf{L})$ is a congruence system of $\mathbb{I}\mathbf{L}$, $\langle I, \pi^{\tilde{\Omega}(\mathbb{I}\mathbf{L})} \rangle : \mathbb{I}\mathbf{L} \rightarrow \mathbb{I}\mathbf{L}^*$ is a bilogical morphism.

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F, \pi^{\tilde{\Omega}(\mathbb{I}\mathbf{L})} \alpha \rangle \\
 \mathbf{A} & \xrightarrow{\langle I, \pi^{\tilde{\Omega}(\mathbb{I}\mathbf{L})} \rangle} & \mathbf{A}^*
 \end{array}$$

And this gives the configuration of the diagram that matches the setup in the hypothesis of Proposition 1420. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system and $\mathbb{I}\mathbf{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. We say that $\mathbb{I}\mathbf{L}$ is an $\mathcal{I}$ -structure or a **model of $\mathcal{I}$** if $C \leq C^{\mathbb{I}\mathbf{L}}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\phi \in C_{\Sigma}(\Phi) \quad \text{implies} \quad \phi \in C_{\Sigma}^{\mathbb{I}\mathbf{L}}(\Phi).$$

Of course, $C \leq C^{\mathbb{I}\mathbf{L}}$ requires that, for all $T \in \text{ThFam}(\mathbb{I}\mathbf{L})$, all $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_{\Sigma}(\Phi)$,

$$\alpha_{\Sigma'}(\text{SEN}^b(f)(\Phi)) \subseteq T_{F(\Sigma')} \quad \text{implies} \quad \alpha_{\Sigma'}(\text{SEN}^b(f)(\phi)) \in T_{F(\Sigma')},$$

i.e., that $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, we obtain the following characterization:

Proposition 1422 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system and $\mathbb{I}\mathbf{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. $\mathbb{I}\mathbf{L}$ is an $\mathcal{I}$ -structure if and only if, for all $T \in \text{ThFam}(\mathbb{I}\mathbf{L})$, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, i.e., if and only if $\text{ThFam}(\mathbb{I}\mathbf{L}) \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$.*

Again, the defining condition of an $\mathcal{I}$ -structure may be simplified due to the structurality of $\mathcal{I}$. More precisely, based on Lemma 50, we have:

Lemma 1423 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. Then, the following conditions are equivalent:*

- (a) $\mathbb{L}$ is an $\mathcal{I}$ -structure;
- (b) For all $T \in \text{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$,

$$\alpha_\Sigma(\Phi) \subseteq T_{F(\Sigma)} \quad \text{implies} \quad \alpha_\Sigma(\phi) \in T_{F(\Sigma)};$$

- (c) For all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$.

Proof: Condition (a) clearly implies (b) and (b) and (c) are equivalent. So it remains to show that (b) implies (a). But, if Condition (b) holds, then, by Lemma 50, $\text{ThFam}(\mathbb{L}) \subseteq \text{FiFam}^\mathcal{I}(\mathcal{A})$, whence, by Proposition 1422, $\mathbb{L}$ is an $\mathcal{I}$ -structure. ■

We denote by $\text{Str}(\mathcal{I})$ the class of all $\mathcal{I}$ -structures and let

$$\text{Str}^*(\mathcal{I}) = (\text{Str}(\mathcal{I}))^*$$

be the class of all reduced $\mathcal{I}$ -structures.

Since we know that $\mathbb{L} \in \text{Str}(\mathcal{I})$ is and only if $\text{ThFam}(\mathbb{L}) \subseteq \text{FiFam}^\mathcal{I}(\mathcal{A})$, it follows that, given an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ is the weakest $\mathcal{I}$ -structure of $\mathcal{A}$, i.e., the one with the finest closure family.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be a base algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We say that $\mathcal{I}$ is **complete with respect to a given class $\mathbf{L}$** of $\mathbf{F}$ -structures if $C = C^\mathbf{L}$, i.e., if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$,

$$\phi \in C_\Sigma(\Phi) \quad \text{iff} \quad \phi \in C_\Sigma^\mathbf{L}(\Phi).$$

As consequences of Proposition 1420 and of its Corollary 1421, we have the following results about models of π -institutions and about classes of structures with respect to which a π -institution is complete.

Proposition 1424 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) *If $\langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ are $\mathbf{F}$ -structures and $\langle G, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism, the $\mathbb{L}$ is an $\mathcal{I}$ -structure if and only if $\mathbb{L}'$ is an $\mathcal{I}$ -structure.*
- (b) *If $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is an $\mathbf{F}$ -structure, then $\mathbb{L}$ is an $\mathcal{I}$ -structure if and only if $\mathbb{L}^*$ is an $\mathcal{I}$ -structure.*
- (c) *If $\mathcal{I}$ is complete with respect to a class $\mathbf{L}$ of $\mathbf{F}$ -structures, then it is also complete with respect to $\mathbf{L}^*$.*

Proof: the first part is a consequence of Proposition 1420, whereas Parts (b) and (c) follow directly from Corollary 1421. ■

Proposition 1425 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathbf{L}$ a class of $\mathcal{I}$ -structures. If $\mathbf{L}$ includes $\langle \mathcal{F}, C \rangle$ or $\langle \mathcal{F}, C \rangle^*$, then $\mathcal{I}$ is complete with respect to both $\mathbf{L}$ and $\mathbf{L}^*$. In particular $\mathcal{I}$ is complete with respect to both $\mathbf{Str}(\mathcal{I})$ and $\mathbf{Str}^*(\mathcal{I})$.*

Proof: The key here is to notice that $C = C^{\langle \mathcal{F}, C \rangle} = C^{\langle \mathcal{F}, C \rangle^*}$. Then, the rest is easy because we have

$$C \leq C^{\mathbf{L}} = C^{\mathbf{L}^*} \leq C^{\langle \mathcal{F}, C \rangle} = C^{\langle \mathcal{F}, C \rangle^*} = C.$$

Therefore, we conclude $C = C^{\mathbf{L}} = C^{\mathbf{L}^*}$ and, hence, $\mathcal{I}$ is complete with respect to both $\mathbf{L}$ and $\mathbf{L}^*$. ■

19.5 Full $\mathcal{I}$ -Structures

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. $\mathbb{L}$ is a **full $\mathcal{I}$ -structure** or a **full model of $\mathcal{I}$** if

$$\mathbb{L}^* = \langle \mathcal{A}^*, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle,$$

i.e., if the closure family of the reduction of $\mathbb{L}$ consists of all $\mathcal{I}$ -filter families on the $\mathbf{F}$ -algebraic system $\mathcal{A}/\widetilde{\Omega}(\mathbb{L})$.

We denote the class of all full $\mathcal{I}$ -structures by $\mathbf{FStr}(\mathcal{I})$ and the class of all reduced full $\mathcal{I}$ -structures by $\mathbf{FStr}^*(\mathcal{I})$. We also write $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$ for the collection of all full $\mathcal{I}$ -structures on the $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$.

We show that full $\mathcal{I}$ -structures are fully deserving of the name $\mathcal{I}$ -structures.

Proposition 1426 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ a full $\mathcal{I}$ -structure.*

- (a) D is structural;
- (b) $\mathbb{L}$ is an $\mathcal{I}$ -structure;
- (c) $\mathbb{L}$ has theorems if and only if $\mathcal{I}$ has theorems.

Proof:

- (a) By Proposition 1412, D^* is structural. Therefore, by Proposition 1403, D is also structural.

- (b) Suppose $\mathbb{L} \in \mathbf{FStr}(\mathcal{I})$. Then, by definition, $\mathbf{ThFam}(\mathbb{L}^*) = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Thus, by Proposition 1422, $\mathbb{L}^* \in \mathbf{Str}(\mathcal{I})$. Therefore, by Proposition 1424, $\mathbb{L} \in \mathbf{Str}(\mathcal{I})$.
- (c) If $\mathcal{I}$ does not have theorems, then $\emptyset \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Therefore, by the definition of a full $\mathcal{I}$ -structure, $\emptyset \in \mathbf{ThFam}(\mathbb{L}^*)$ and, hence $\emptyset \in \mathbf{ThFam}(\mathbb{L})$. Conversely, if $\emptyset \notin \mathbf{ThFam}(\mathcal{I})$, then $\emptyset \notin \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, hence, $\emptyset \notin \mathbf{ThFam}(\mathbb{L})$. ■

We now show that, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the pair $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is always a full $\mathcal{I}$ -structure and, thus, the weakest such structure on $\mathcal{A}$.

Proposition 1427 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is the weakest full $\mathcal{I}$ -structure on $\mathcal{A}$.*

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system. Then, by Corollary 1415,

$$(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}))^* = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}^*).$$

So $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a full $\mathcal{I}$ -structure. Moreover, since, by Proposition 1426, every full $\mathcal{I}$ -structure is an $\mathcal{I}$ -structure, by Proposition 1422, $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ is the largest possible set of theory families of a full $\mathcal{I}$ -structure. So $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is the weakest full $\mathcal{I}$ -structure. ■

Specializing to the algebraic system $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, where $\langle I, \iota \rangle : \mathbf{F} \rightarrow \mathbf{F}$ is the identity morphism, we get

Corollary 1428 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Then $\langle \mathcal{F}, C \rangle$ is the weakest full $\mathcal{I}$ -structure on $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$.*

Proof: By taking $\mathcal{A} = \mathcal{F}$ in Proposition 1427. ■

Next, we see that biological morphisms between $\mathbf{F}$ -structures preserve the property of being a full model in both directions.

Proposition 1429 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ two $\mathbf{F}$ -algebraic systems and $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ two $\mathbf{F}$ -structures. If there exists a biological morphism $\langle G, \beta \rangle : \mathbb{L} \vdash \mathbb{L}'$, then $\mathbb{L}$ is a full $\mathcal{I}$ -structure if and only if $\mathbb{L}'$ is a full $\mathcal{I}$ -structure.*

Proof: Suppose $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle$ and $\mathbb{I}\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ are two $\mathbf{F}$ -structures and let $\langle G, \beta \rangle : \mathbb{I}\mathbb{L} \vdash \mathbb{I}\mathbb{L}'$ be a biological morphism. Then, by Proposition 1409, there exists an α -isomorphism $\langle G, \gamma \rangle : \mathbb{I}\mathbb{L}^* \vdash^\alpha \mathbb{I}\mathbb{L}'^*$, such that the following diagram commutes.

$$\begin{array}{ccc}
 & \mathbf{F} & \\
 \langle F, \alpha \rangle \swarrow & & \searrow \langle F', \alpha' \rangle \\
 \mathbf{A} & \xrightarrow{\langle G, \beta \rangle} & \mathbf{A}' \\
 \langle I, \pi \rangle \downarrow & & \downarrow \langle I', \pi' \rangle \\
 \mathbf{A}^* & \xrightarrow{\langle G, \gamma \rangle} & \mathbf{A}'^*
 \end{array}$$

where $\langle I, \pi \rangle : \mathbf{A} \rightarrow \mathbf{A}/\widetilde{\Omega}(\mathbb{I}\mathbb{L})$ and $\langle I', \pi' \rangle : \mathbf{A}' \rightarrow \mathbf{A}'/\widetilde{\Omega}(\mathbb{I}\mathbb{L}')$ denote the quotient morphisms. If $\mathbb{I}\mathbb{L}$ is a full $\mathcal{I}$ -structure, then, by definition, $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Thus, by Proposition 1414, $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}'^*)$. This shows that $\mathbb{I}\mathbb{L}'$ is a full $\mathcal{I}$ -structure. If, conversely, $\mathbb{I}\mathbb{L}'$ is a full $\mathcal{I}$ -structure, then, by definition $\mathcal{D}'^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}'^*)$. Thus, by Proposition 1417, $\mathcal{D} = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and, therefore, $\mathbb{I}\mathbb{L}$ is a full $\mathcal{I}$ -structure, by definition. ■

Proposition 1429 allows the formulation of a characterizing property of full $\mathcal{I}$ -structures in terms of biological morphisms and weakest full $\mathcal{I}$ -structures.

Corollary 1430 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. $\mathbb{I}\mathbb{L}$ is a full $\mathcal{I}$ -structure if and only if there exists a biological morphism from $\mathbb{I}\mathbb{L}$ onto an $\mathbf{F}$ -structure of the form $\langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle$, for some $\mathbf{F}$ -algebraic system $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$.*

Proof: The “only if” is clear, since, if $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a full $\mathcal{I}$ -structure, then $\langle I, \pi \rangle : \mathbb{I}\mathbb{L} \vdash \mathbb{I}\mathbb{L}^*$ is a biological morphism and, moreover, by the definition of fullness, $\mathbb{I}\mathbb{L}^* = \langle \mathcal{A}^*, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$.

Assume, conversely, that $\langle H, \gamma \rangle : \mathbb{I}\mathbb{L} \vdash \langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle$ is a biological morphism. By Proposition 1427, $\langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle \in \text{FStr}(\mathcal{I})$. Therefore, by Proposition 1429, $\mathbb{I}\mathbb{L} \in \text{FStr}(\mathcal{I})$, as well. ■

We now formulate a result that can be used to show that a property of $\mathbf{F}$ -structures for every full $\mathcal{I}$ -structure of a π -institution $\mathcal{I}$ based on $\mathbf{F}$. It characterizes $\text{FStr}(\mathcal{I})$ as the smallest class of $\mathbf{F}$ -structures containing all $\mathbf{F}$ -structures of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$, with $\mathcal{A}$ ranging over all $\mathbf{F}$ -algebraic systems, and closed under biological morphisms. It follows that to prove that a property holds for all members of $\text{FStr}(\mathcal{I})$ it suffices to show that it holds for all $\mathbf{F}$ -structures of the specific form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ and that it is preserved under biological morphisms.

Corollary 1431 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. $\mathbf{FStr}(\mathcal{I})$ is the smallest class containing $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and closed under both images and preimages under biological morphisms.*

Proof: By Proposition 1427, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the pair $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \in \mathbf{FStr}(\mathcal{I})$. Moreover, by Proposition 1429, $\mathbf{FStr}(\mathcal{I})$ is closed under both images and preimages under biological morphisms. On the other hand, let $\mathbf{L}$ be a class satisfying these properties and let $\langle \mathcal{A}, D \rangle \in \mathbf{FStr}(\mathcal{I})$. By Corollary 1430, there exists an $\mathbf{F}$ -algebraic system $\mathcal{A}'$ and a biological morphism

$$\langle H, \gamma \rangle : \langle \mathcal{A}, D \rangle \mapsto \langle \mathcal{A}', \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle.$$

By hypothesis, $\langle \mathcal{A}', \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle \in \mathbf{L}$ and, again by hypothesis, $\langle \mathcal{A}, D \rangle \in \mathbf{L}$. Thus, we conclude that $\mathbf{FStr}(\mathcal{I}) \subseteq \mathbf{L}$. This proves that $\mathbf{FStr}(\mathcal{I})$ is indeed the smallest class satisfying the given properties. ■

An alternative characterization of full $\mathcal{I}$ -structures uses both the Leibniz and the Tarski operators.

Theorem 1432 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. Then $\mathbb{L}$ is a full $\mathcal{I}$ -structure if and only if*

$$\mathcal{D} = \{T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) : \tilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)\}.$$

Proof: Let $\mathbb{L}$ be an $\mathbf{F}$ -structure and set

$$\mathcal{T} = \{T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) : \tilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)\}.$$

Suppose, first, that $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathbf{FStr}(\mathcal{I})$. We must show $\mathcal{D} = \mathcal{T}$. To this end, let $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then, by Proposition 1422, $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by the definition of the Tarski congruence system, $\tilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)$. Thus, $\mathcal{D} \subseteq \mathcal{T}$. Conversely, if $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)$, then $\tilde{\Omega}(\mathbb{L})$ is compatible with T . Setting $T' = T/\tilde{\Omega}(\mathbb{L})$, we have, by Corollary 56, that $T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}(\mathbb{L}))$ and $T = \pi^{-1}(T')$, where $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\tilde{\Omega}(\mathbb{L})$ is the quotient morphism, which is also a biological morphism $\langle I, \pi \rangle : \mathbb{L} \mapsto \mathbb{L}^*$. Since, by hypothesis $\mathbb{L}$ is full, we get that $\mathcal{D}^* = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}(\mathbb{L}))$, whence, $T = \pi^{-1}(T') \in \pi^{-1}(\mathcal{D}^*) = \mathcal{D}$. We conclude that $\mathcal{T} \subseteq \mathcal{D}$.

Assume, conversely, that $\mathcal{D} = \{T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) : \tilde{\Omega}(\mathbb{L}) \leq \Omega^{\mathcal{A}}(T)\}$. Then, by Proposition 1397,

$$\langle I, \pi \rangle : \mathbb{L} \mapsto \langle \mathcal{A}/\tilde{\Omega}(\mathbb{L}), \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}(\mathbb{L})) \rangle$$

is a biological morphism. Therefore, $\mathcal{D}^* = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\tilde{\Omega}(\mathbb{L}))$, showing that $\mathbb{L} \in \mathbf{FStr}(\mathcal{I})$. ■

19.6 $\mathcal{I}$ -Algebraic Systems

Since $\langle \mathcal{A}, \mathcal{D} \rangle$ is a full $\mathcal{I}$ -structure if and only if $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$, we conclude that the reduced full $\mathcal{I}$ -structures are exactly those structures of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$, which are reduced.

Definition 1433 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. An $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ is an $\mathcal{I}$ -algebraic system if and only if the $\mathbf{F}$ -structure $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is reduced, i.e., if $\mathcal{A}$ is the underlying $\mathbf{F}$ -algebraic system of a reduced full $\mathcal{I}$ -structure.

We denote by $\text{AlgSys}(\mathcal{I})$ the class of all $\mathcal{I}$ -algebraic systems.

Since $\mathcal{I}$ -algebraic systems are determined based on reduced full $\mathcal{I}$ -structures, the following characterization is useful in this context.

Proposition 1434 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. Then the following are equivalent:

- (i) $\mathbb{L}$ is a reduced full $\mathcal{I}$ -structure;
- (ii) $\mathbb{L}$ is reduced and $D = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$;
- (iii) $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$ and $D = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proof:

- (i) $\Rightarrow$ (ii) Suppose that $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a reduced full $\mathcal{I}$ -structure. Since $\mathbb{L}$ is full, $\mathbb{L}^* = \langle \mathcal{A}^*, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$. Since $\mathbb{L}$ is reduced, $\mathbb{L}^* = \mathbb{L}$. Thus, $D = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$.
- (ii) $\Rightarrow$ (ii) Assume $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is reduced and $D = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\mathbb{L}$ is reduced, $\mathbb{L}^* = \mathbb{L} = \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$. Therefore, $\mathbb{L}$ is also full and, consequently, $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$.
- (iii) $\Rightarrow$ (i) Let $\mathbb{L} = \langle \mathcal{A}, D \rangle$, with $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$ and $D = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$, there exists a closure family D' on $\mathcal{A}$, such that $\langle \mathcal{A}, D' \rangle$ is a reduced full $\mathcal{I}$ -structure. Since $\langle \mathcal{A}, D' \rangle$ is full and reduced, we have $D' = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since, by hypothesis, $D = \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we get that $D' = D$. Hence, $\mathbb{L} = \langle \mathcal{A}, D \rangle = \langle \mathcal{A}, D' \rangle$ is a reduced full $\mathcal{I}$ -structure. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Let, also, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. We denote by $\text{ConSys}^{\mathcal{I}}(\mathcal{A})$ the collection of all congruence systems θ on $\mathcal{A}$, such that the quotient algebraic system $\mathcal{A}^\theta$ is in $\text{AlgSys}(\mathcal{I})$:

$$\text{ConSys}^{\mathcal{I}}(\mathcal{A}) = \{ \theta \in \text{ConSys}(\mathcal{A}) : \mathcal{A}^\theta \in \text{AlgSys}(\mathcal{I}) \}.$$

A congruence system $\theta \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$ is called an $\mathcal{I}$ -congruence system on $\mathcal{A}$.

It turns out that the Tarski congruence systems of full $\mathcal{I}$ -structures are all $\mathcal{I}$ -congruence systems.

Proposition 1435 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. If $\mathbb{L}$ is full, then $\mathcal{A}^* \in \text{AlgSys}(\mathcal{I})$ and, therefore, $\tilde{\Omega}(\mathbb{L}) \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$.*

Proof: Suppose that $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a full $\mathcal{I}$ -structure. Then, by definition, $\mathbb{L}^* = \langle \mathcal{A}^*, \mathcal{D}^* \rangle = \langle \mathcal{A}^*, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$ is a reduced full $\mathcal{I}$ -structure. Hence $\mathcal{A}^* \in \text{AlgSys}(\mathcal{I})$ and, therefore, by definition, $\tilde{\Omega}(\mathbb{L}) \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. ■

Even though, according to the definition, $\mathcal{I}$ -algebraic systems are determined as the $\mathbf{F}$ -algebraic system reducts of reduced full $\mathcal{I}$ -structures, they can also be characterized without reference to fullness.

Proposition 1436 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\text{AlgSys}(\mathcal{I})$ is the class of all underlying $\mathbf{F}$ -algebraic systems of all reduced $\mathcal{I}$ -structures:*

$$\text{AlgSys}(\mathcal{I}) = \{ \mathcal{A} : (\exists \langle \mathcal{A}, D \rangle \in \text{Str}^{\mathcal{I}}(\mathcal{A})) (\tilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Delta^{\mathcal{A}}) \}.$$

Proof: If $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$, then, by Proposition 1434, $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$ -structure. Conversely, if $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a reduced $\mathcal{I}$ -structure, then $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, therefore,

$$\tilde{\Omega}(\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle) \leq \tilde{\Omega}(\mathbb{L}) = \Delta^{\mathcal{A}}.$$

Thus, $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$ -structure and $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$. ■

The class of all $\mathcal{I}$ -algebraic systems is closed under isomorphisms.

Proposition 1437 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\text{AlgSys}(\mathcal{I})$ is closed under isomorphisms.*

Proof: Assume $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle \in \text{AlgSys}(\mathcal{I})$ and let $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ be an isomorphism.

Then, we have that $\text{FiFam}^{\mathcal{I}}(\mathcal{A}) = \gamma^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{B}))$, which shows that

$$\langle H, \gamma \rangle : \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \cong \langle \mathcal{B}, \text{FiFam}^{\mathcal{I}}(\mathcal{B}) \rangle.$$

Now we can use Proposition 1400 to see that $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is reduced if and only if $\langle \mathcal{B}, \text{FiFam}^{\mathcal{I}}(\mathcal{B}) \rangle$ is reduced and, therefore, by Proposition 1436, $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$ if and only if $\mathcal{B} \in \text{AlgSys}(\mathcal{I})$. ■

Proposition 1434 gave characterizing conditions for reduced full $\mathcal{I}$ -structures. An analog for full $\mathcal{I}$ -structures is the following:

Proposition 1438 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. Then the following are equivalent:*

- (i) $\mathbb{L}$ is a full $\mathcal{I}$ -structure;
- (ii) $\mathcal{A}^* \in \text{AlgSys}(\mathcal{I})$ and $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$;
- (iii) There exists a biological morphism $\langle H, \gamma \rangle : \mathbb{L} \vdash \langle \mathcal{A}', D' \rangle$, such that $\mathcal{A}' \in \text{AlgSys}(\mathcal{I})$ and $\mathcal{D}' = \text{FiFam}^{\mathcal{I}}(\mathcal{A}')$.

Proof:

- (i) $\Rightarrow$ (ii) Suppose $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a full $\mathcal{I}$ -structure. Then, by definition, $\mathbb{L}^* = \langle \mathcal{A}^*, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$. Thus, $\mathcal{A}^* \in \text{AlgSys}(\mathcal{I})$ and $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.
- (ii) $\Rightarrow$ (iii) Obvious, since $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a biological morphism.
- (iii) $\Rightarrow$ (i) Assume that $\langle H, \gamma \rangle : \mathbb{L} \rightarrow \langle \mathcal{A}', D' \rangle$ is a biological morphism, such that $\mathcal{A}' \in \text{AlgSys}(\mathcal{I})$ and $\mathcal{D}' = \text{FiFam}^{\mathcal{I}}(\mathcal{A}')$. Then, by Proposition 1409, there exists an α -isomorphism $\mathbb{L}^* \vdash^\alpha \langle \mathcal{A}'^*, \mathcal{D}'^* \rangle$. Since $\mathcal{A}' \in \text{AlgSys}(\mathcal{I})$ and $\mathcal{D}' = \text{FiFam}^{\mathcal{I}}(\mathcal{A}')$, it follows, by Proposition 1434, that $\langle \mathcal{A}', D' \rangle$ is a reduced full $\mathcal{I}$ -structure. So we have

$$\langle \mathcal{A}'^*, \mathcal{D}'^* \rangle = \langle \mathcal{A}', D' \rangle = \langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle.$$

Hence, by Proposition 1417, $\mathbb{L}^* = \langle \mathcal{A}^*, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \rangle$ and, therefore, $\mathbb{L}$ is a full $\mathcal{I}$ -structure. ■

It turns out that, given a π -institution $\mathcal{I}$, the class of all full $\mathcal{I}$ -structures, the class of all $\mathbf{F}$ -structures of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$, where $\mathcal{A}$ ranges over all $\mathbf{F}$ -algebraic systems, as well as the class of all reduced full $\mathcal{I}$ -structures are complete $\mathbf{F}$ -structure semantics for $\mathcal{I}$.

Theorem 1439 (Completeness Theorem) *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is complete with respect to the following classes of $\mathbf{F}$ -structures:*

- (i) The class of all full $\mathcal{I}$ -structures;
- (ii) The class of all $\mathbf{F}$ -structures of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$;
- (iii) The class of all reduced full $\mathcal{I}$ -structures, i.e., structures of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$, with $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$.

Proof: Note that all three classes of $\mathbf{F}$ -structures consist of $\mathcal{I}$ -structures and include $\langle \mathcal{F}, C \rangle^*$. Therefore, by Proposition 1425, $\mathcal{I}$ is complete with respect to each one of them. ■

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution. To $\mathcal{I}$ we have associated (among others) two classes of $\mathbf{F}$ -algebraic systems. One is the class $\text{AlgSys}^*(\mathcal{I})$ of underlying $\mathbf{F}$ -algebraic systems of reduced $\mathcal{I}$ -matrix families. The other is the class $\text{AlgSys}(\mathcal{I})$ of underlying $\mathbf{F}$ -algebraic systems of reduced $\mathcal{I}$ -structures (according to Proposition 1436). To explore an important relationship between these two classes, we introduce an operator on $\mathbf{F}$ -algebraic systems, which is related to an operator on $\mathbf{F}$ -matrix families, given the same name.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and consider $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{A}^i = \langle \mathbf{A}^i, \langle F^i, \alpha^i \rangle \rangle$, $i \in I$, and a system of surjective morphisms

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle F^i, \alpha^i \rangle \\ \mathbf{A} & \xrightarrow{\langle H^i, \gamma^i \rangle} & \mathbf{A}^i \end{array}$$

We say $\{\langle H^i, \gamma^i \rangle : i \in I\}$ is a **subdirect intersection (system)** and call the $\langle H^i, \gamma^i \rangle$ **subdirect intersection morphisms** if

$$\bigcap_{i \in I} \text{Ker}(\langle H^i, \gamma^i \rangle) = \Delta^{\mathcal{A}}.$$

If such a system exists, we say that $\mathcal{A}$ is a **subdirect intersection** of the $\mathbf{F}$ -algebraic systems $\{\mathcal{A}^i : i \in I\}$. Given a class $\mathbf{K}$ of $\mathbf{F}$ -algebraic systems and an $\mathbf{F}$ -algebraic system $\mathcal{A}$, we write

$$\mathcal{A} \in \overset{\triangleleft}{\text{III}}(\mathbf{K})$$

to signify that $\mathcal{A}$ is a subdirect intersection of a collection $\{\mathcal{A}^i : i \in I\}$, with $\mathcal{A}^i \in \mathbf{K}$, for all $i \in I$.

We can show that the operator $\overset{\triangleleft}{\text{III}}$ is a closure operator on classes of $\mathbf{F}$ -algebraic systems.

Proposition 1440 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system. Then*

$$\overset{\triangleleft}{\Pi} : \mathcal{P}(\text{AlgSys}(\mathbf{F})) \rightarrow \mathcal{P}(\text{AlgSys}(\mathbf{F}))$$

is a closure operator.

Proof: Suppose, first, that $\mathbf{K} \subseteq \text{AlgSys}(\mathbf{F})$ and $\mathcal{A} \in \mathbf{K}$. Since the identity morphism $\langle I, \iota \rangle : \mathcal{A} \rightarrow \mathcal{A}$ is a subdirect intersection, we get that $\mathcal{A} \in \overset{\triangleleft}{\Pi}(\mathbf{K})$. Thus, $\overset{\triangleleft}{\Pi}$ is inflationary.

Suppose, next, that $\mathbf{K} \subseteq \mathbf{K}' \subseteq \text{AlgSys}(\mathbf{F})$ and $\mathcal{A} \in \overset{\triangleleft}{\Pi}(\mathbf{K})$. Thus, $\mathcal{A}$ is a subdirect intersection of a collection $\{\mathcal{A}^i : i \in I\} \subseteq \mathbf{K}$. Then $\mathcal{A}$ is a subdirect intersection of $\{\mathcal{A}^i : i \in I\} \subseteq \mathbf{K}'$. Hence, $\overset{\triangleleft}{\Pi}(\mathbf{K}) \subseteq \overset{\triangleleft}{\Pi}(\mathbf{K}')$ and, therefore, $\overset{\triangleleft}{\Pi}$ is also monotone.

Assume, finally, that $\mathbf{K} \subseteq \text{AlgSys}(\mathbf{F})$ and let $\mathcal{A} \in \overset{\triangleleft}{\Pi}(\overset{\triangleleft}{\Pi}(\mathbf{K}))$. Thus, there exists a subdirect intersection system

$$\langle H^i, \gamma^i \rangle : \mathcal{A} \rightarrow \mathcal{A}^i, \quad i \in I,$$

where $\mathcal{A}^i \in \overset{\triangleleft}{\Pi}(\mathbf{K})$, for all $i \in I$. Consequently, for all $i \in I$, there exists a subdirect intersection system

$$\langle H^{ij}, \gamma^{ij} \rangle : \mathcal{A}^i \rightarrow \mathcal{A}^{ij}, \quad j \in J_i,$$

where $\mathcal{A}^{ij} \in \mathbf{K}$, for all $i \in I, j \in J_i$. We consider the collection

$$\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle : \mathcal{A} \rightarrow \mathcal{A}^{ij}, \quad i \in I, j \in J_i.$$

We have

$$\begin{aligned} \bigcap_{i \in I} \bigcap_{j \in J_i} \text{Ker}(\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle) &= \bigcap_{i \in I} \bigcap_{j \in J_i} (\gamma^i)^{-1}(\text{Ker}(\langle H^{ij}, \gamma^{ij} \rangle)) \\ &= \bigcap_{i \in I} (\gamma^i)^{-1}(\bigcap_{j \in J_i} (\text{Ker}(\langle H^{ij}, \gamma^{ij} \rangle))) \\ &= \bigcap_{i \in I} (\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}) \\ &= \bigcap_{i \in I} \text{Ker}(\langle H^i, \gamma^i \rangle) \\ &= \Delta^{\mathcal{A}}. \end{aligned}$$

Thus, the system $\{\langle H^{ij}, \gamma^{ij} \rangle \circ \langle H^i, \gamma^i \rangle : i \in I, j \in J_i\}$ is a subdirect intersection system, showing that $\mathcal{A} \in \overset{\triangleleft}{\Pi}(\mathbf{K})$. We conclude that $\overset{\triangleleft}{\Pi}$ is also idempotent. ■

Using subdirect intersections, we can give the exact relationship between the classes $\text{AlgSys}(\mathcal{I})$ and $\text{AlgSys}^*(\mathcal{I})$. Namely, we show that the former is the class of all subdirect intersections of collections of algebraic systems in the latter class. In particular $\text{AlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}(\mathcal{I})$.

Theorem 1441 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then*

$$\text{AlgSys}(\mathcal{I}) = \overset{\triangleleft}{\Pi}(\text{AlgSys}^*(\mathcal{I})).$$

Proof: Assume, first, that $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$. Then, we have

$$\bigcap \{\Omega^{\mathcal{A}}(T) : T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} = \widetilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) = \Delta^{\mathcal{A}}.$$

Now, consider the collection

$$\langle I, \pi^{\Omega^{\mathcal{A}}(T)} : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T), \quad T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

By the preceding equation, this collection constitutes a subdirect intersection. Moreover, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have $\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle \in \text{MatFam}^*(\mathcal{I})$ and, hence, $\mathcal{A}/\Omega^{\mathcal{A}}(T) \in \text{AlgSys}^*(\mathcal{I})$. Therefore, we get that $\mathcal{A} \in \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I}))$.

Suppose, conversely, that $\mathcal{A} \in \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I}))$. Thus, there exists a subdirect intersection

$$\langle H^i \gamma^i : \mathcal{A} \rightarrow \mathcal{A}^i, \quad i \in I,$$

with $\mathcal{A}^i \in \text{AlgSys}^*(\mathcal{I})$, for all $i \in I$. Thus, for all $i \in I$, there exists $T^i \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^i)$, such that $\Omega^{\mathcal{A}^i}(T^i) = \Delta^{\mathcal{A}^i}$. Now, we calculate:

$$\begin{aligned} \widetilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) &= \bigcap \{\Omega^{\mathcal{A}}(T) : T \in \text{ThFam}^{\mathcal{I}}(\mathcal{A})\} \\ &\subseteq \bigcap_{i \in I} \Omega^{\mathcal{A}}((\gamma^i)^{-1}(T^i)) \\ &= \bigcap_{i \in I} (\gamma^i)^{-1}(\Omega^{\mathcal{A}^i}(T^i)) \\ &= \bigcap_{i \in I} (\gamma^i)^{-1}(\Delta^{\mathcal{A}^i}) \\ &= \bigcap_{i \in I} \text{Ker}(\langle H^i, \gamma^i \rangle) \\ &= \Delta^{\mathcal{A}}. \end{aligned}$$

We conclude that $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$. Thus, $\text{AlgSys}(\mathcal{I}) \subseteq \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I}))$. ■

Corollary 1442 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $\text{AlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}(\mathcal{I})$ and, moreover, $\text{AlgSys}^*(\mathcal{I}) = \text{AlgSys}(\mathcal{I})$ if and only if $\text{AlgSys}^*(\mathcal{I})$ is closed under subdirect intersections.*

Proof: We have

$$\begin{aligned} \text{AlgSys}^*(\mathcal{I}) &\subseteq \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I})) \quad (\text{by Proposition 1440}) \\ &= \text{AlgSys}(\mathcal{I}). \quad (\text{by Theorem 1441}) \end{aligned}$$

If $\text{AlgSys}^*(\mathcal{I})$ is closed under subdirect intersections,

$$\text{AlgSys}(\mathcal{I}) = \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I})) \subseteq \text{AlgSys}^*(\mathcal{I}).$$

Conversely, if $\text{AlgSys}^*(\mathcal{I}) = \text{AlgSys}(\mathcal{I})$, then $\overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I})) = \text{AlgSys}(\mathcal{I}) = \text{AlgSys}^*(\mathcal{I})$. ■

Finally, we give a relation between the classes of algebraic systems associated in this way with π -institutions based on the same algebraic system that are related by $\leq$. Recall that, given $\mathcal{I} = \langle \mathbf{F}, C \rangle$ and $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$, we write $C \leq C'$ if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \subseteq \text{SEN}^b(\Sigma)$, $C_\Sigma(\Phi) \subseteq C'_\Sigma(\Phi)$. If this is the case, we also write $\mathcal{I} \leq \mathcal{I}'$ and say that $\mathcal{I}'$ is stronger than $\mathcal{I}$ and that $\mathcal{I}$ is weaker than $\mathcal{I}'$. Recall, also, that, $\mathcal{I} \leq \mathcal{I}'$ if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, $\text{FiFam}^{\mathcal{I}'}(\mathcal{A}) \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proposition 1443 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$, $\mathcal{I}' = \langle \mathbf{F}, C' \rangle$ be two π -institutions based on $\mathbf{F}$. If $\mathcal{I} \leq \mathcal{I}'$, then*

$$\text{AlgSys}(\mathcal{I}') \subseteq \text{AlgSys}(\mathcal{I}) \quad \text{and} \quad \text{AlgSys}^*(\mathcal{I}') \subseteq \text{AlgSys}^*(\mathcal{I}).$$

Proof: If $\mathcal{A} \in \text{AlgSys}^*(\mathcal{I}')$, then, there exists $T' \in \text{FiFam}^{\mathcal{I}'}(\mathcal{A})$, such that $\Omega^{\mathcal{A}}(T') = \Delta^{\mathcal{A}}$. But, since $\mathcal{I} \leq \mathcal{I}'$, we have $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore $\mathcal{A} \in \text{AlgSys}^*(\mathcal{I})$. We now conclude that $\text{AlgSys}^*(\mathcal{I}') \subseteq \text{AlgSys}^*(\mathcal{I})$.

For the second inclusion, we get

$$\begin{aligned} \text{AlgSys}(\mathcal{I}') &= \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I})) \quad (\text{Theorem 1441}) \\ &\subseteq \overset{\triangleleft}{\text{III}}(\text{AlgSys}^*(\mathcal{I})) \quad (\text{Proposition 1440}) \\ &= \text{AlgSys}(\mathcal{I}). \quad (\text{Theorem 1441}) \end{aligned}$$

■

19.7 Lattice of Full $\mathcal{I}$ -Structures

In this section we show that, given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ and an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{F}, \langle F, \alpha \rangle \rangle$, the poset $\langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ of full $\mathcal{I}$ -structures on $\mathcal{A}$ and the poset $\langle \text{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ of $\mathcal{I}$ -congruence systems on $\mathcal{A}$ are isomorphic through the Tarski operator

$$\langle \mathcal{A}, D \rangle \mapsto \tilde{\Omega}^{\mathcal{A}}(D).$$

We start by defining an operator which will turn out to be the inverse of the Tarski operator.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. Given $\theta \in \text{ConSys}(\mathcal{A})$, define

$$\tilde{H}^{\mathcal{A}}(\theta) = \langle \mathcal{A}, \mathcal{D}^\theta \rangle,$$

by setting

$$\mathcal{D}^\theta = (\pi^\theta)^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)),$$

where $\langle I, \pi^\theta \rangle : \mathcal{A} \rightarrow \mathcal{A}^\theta$ is the quotient morphism.

Note that, by definition of $\tilde{H}^{\mathcal{A}}(\theta)$, the morphism

$$\langle I, \pi^\theta \rangle : \tilde{H}^{\mathcal{A}}(\theta) \rightarrow \langle \mathcal{A}^\theta, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle$$

is a bilogical morphism.

We have the following properties concerning the operator $\tilde{H}$.

Lemma 1444 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system.*

- (a) For every $\theta \in \text{ConSys}(\mathcal{A})$,
- (i) $\theta \in \text{ConSys}(\tilde{H}^{\mathcal{A}}(\theta))$;
 - (ii) $\tilde{H}^{\mathcal{A}}(\theta)/\theta = \langle \mathcal{A}^\theta, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle$;
 - (iii) $\tilde{H}^{\mathcal{A}}(\theta) \in \text{FStr}^{\mathcal{I}}(\mathcal{A})$;
- (b) $\theta \mapsto \tilde{H}^{\mathcal{A}}(\theta)$ is order preserving, i.e., for all $\theta, \theta' \in \text{ConSys}(\mathcal{A})$, $\theta \leq \theta'$ implies $\tilde{H}^{\mathcal{A}}(\theta) \leq \tilde{H}^{\mathcal{A}}(\theta')$.

Proof:

- (a) For Part (i) we must show that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$, $\langle \phi, \psi \rangle \in \theta_\Sigma$ implies that $D_\Sigma^\theta(\phi) = D_\Sigma^\theta(\psi)$. Suppose, to this end, that $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$. Then, we have

$$C_\Sigma^{\mathcal{I}, \mathcal{A}^\theta}(\phi/\theta_\Sigma) = C_\Sigma^{\mathcal{I}, \mathcal{A}^\theta}(\psi/\theta_\Sigma),$$

i.e., $C_\Sigma^{\mathcal{I}, \mathcal{A}^\theta}(\pi_\Sigma^\theta(\phi)) = C_\Sigma^{\mathcal{I}, \mathcal{A}^\theta}(\pi_\Sigma^\theta(\psi))$. This gives that

$$(\pi_\Sigma^\theta)^{-1}(C_\Sigma^{\mathcal{I}, \mathcal{A}^\theta}(\pi_\Sigma^\theta(\phi))) = (\pi_\Sigma^\theta)^{-1}(C_\Sigma^{\mathcal{I}, \mathcal{A}^\theta}(\pi_\Sigma^\theta(\psi))).$$

Since $\langle I, \pi^\theta \rangle : \tilde{H}^{\mathcal{A}}(\theta) \rightarrow \langle \mathcal{A}^\theta, C^{\mathcal{I}, \mathcal{A}^\theta} \rangle$ is a biological morphism, we get by Proposition 1397, $D_\Sigma^\theta(\phi) = D_\Sigma^\theta(\psi)$. We conclude that $\theta \in \text{ConSys}(\tilde{H}^{\mathcal{A}}(\theta))$.

For Part (ii), we have

$$\pi^\theta(\mathcal{D}^\theta) = \pi^\theta((\pi^\theta)^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta))) = \text{FiFam}^{\mathcal{A}}(\mathcal{A}^\theta),$$

where the last equality follows from the fact that $\langle I, \pi^\theta \rangle$ is a biological morphism, by applying Proposition 1397.

Part (iii) follows from the fact that the morphism $\langle I, \pi^\theta \rangle : \tilde{H}^{\mathcal{A}}(\theta) \rightarrow \langle \mathcal{A}^\theta, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta) \rangle$ is a biological morphism and Corollary 1430.

- (b) Suppose $\theta, \theta' \in \text{ConSys}(\mathcal{A})$, such that $\theta \leq \theta'$. Then we have the following commutative diagram of $\mathbf{F}$ -algebraic systems.

$$\begin{array}{ccc} \mathcal{A} & \xrightarrow{\langle I, \pi^\theta \rangle} & \mathcal{A}^\theta \\ & \searrow \langle I, \pi^{\theta'} \rangle & \downarrow \langle I, \pi \rangle \\ & & \mathcal{A}^{\theta'} \end{array}$$

where, $\langle I, \pi \rangle : \mathcal{A}^\theta \rightarrow \mathcal{A}^{\theta'}$ is defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, by

$$\pi_\Sigma(\phi/\theta_\Sigma) = \phi/\theta'_\Sigma.$$

Taking this diagram into account, we have

$$\begin{aligned}
 \mathcal{D}^{\theta'} &= (\pi^{\theta'})^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta'})) \quad (\text{Definition of } \mathcal{D}^{\theta'}) \\
 &= (\pi^{\theta})^{-1}(\pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta'}))) \quad (\pi \circ \pi^{\theta} = \pi^{\theta'}) \\
 &\subseteq (\pi^{\theta})^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta})) \quad (\text{Corollary 55}) \\
 &= \mathcal{D}^{\theta}. \quad (\text{Definition of } \mathcal{D}^{\theta})
 \end{aligned}$$

Thus, we get $\tilde{H}^{\mathcal{A}}(\theta) \leq \tilde{H}^{\mathcal{A}}(\theta')$. ■

We are ready now for the main isomorphism theorem that was promised at the beginning of the section.

Theorem 1445 (Isomorphism Theorem) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, an $\mathbf{F}$ -algebraic system. Then*

$$\tilde{\Omega}^{\mathcal{A}} : \langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle \rightarrow \langle \text{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$$

is an order isomorphism, with inverse

$$\tilde{H}^{\mathcal{A}} : \langle \text{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle \rightarrow \langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle.$$

Proof: By Proposition 1435, if $\mathbb{I} \in \text{FStr}^{\mathcal{I}}(\mathcal{A})$, then $\tilde{\Omega}^{\mathcal{A}}(\mathbb{I}) \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. Moreover, by Lemma 1444, if $\theta \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$, then $\tilde{H}^{\mathcal{A}}(\theta) \in \text{FStr}^{\mathcal{I}}(\mathcal{A})$. So, both $\tilde{\Omega}^{\mathcal{A}}$ and $\tilde{H}^{\mathcal{A}}$ are well-defined, with domains and codomains as indicated.

We show, next, that they are mutually inverse mappings.

Suppose, first, that $\mathbb{I} = \langle \mathcal{A}, D \rangle \in \text{FStr}^{\mathcal{I}}(\mathcal{A})$. Then, by Proposition 1435, $\mathcal{A}^* \in \text{AlgSys}^{\mathcal{I}}(\mathcal{A})$ and $\tilde{\Omega}^{\mathcal{A}}(\mathbb{I}) \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. By fullness, $\mathcal{D} = \pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^*))$, where $\langle I, \pi \rangle : \mathbb{I} \vdash \mathbb{I}^*$ is the quotient biological morphism. Then, by definition of $\tilde{H}^{\mathcal{A}}$, we get that $\tilde{H}^{\mathcal{A}}(\tilde{\Omega}^{\mathcal{A}}(\mathbb{I})) = \mathbb{I}$.

Suppose, on the other hand, that $\theta \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. By definition, $\mathcal{A}^{\theta} \in \text{AlgSys}(\mathcal{I})$. Thus, by definition,

$$\langle \mathcal{A}^{\theta}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta}) \rangle \in \text{FStr}(\mathcal{I}) \quad \text{and} \quad \tilde{\Omega}^{\mathcal{A}^{\theta}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta})) = \Delta^{\mathcal{A}^{\theta}}.$$

Now, we get

$$\begin{aligned}
 \tilde{\Omega}^{\mathcal{A}}(\tilde{H}^{\mathcal{A}}(\theta)) &= \tilde{\Omega}^{\mathcal{A}}((\pi^{\theta})^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta}))) \quad (\text{Definition of } \tilde{H}^{\mathcal{A}}(\theta)) \\
 &= (\pi^{\theta})^{-1}(\tilde{\Omega}^{\mathcal{A}^{\theta}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta}))) \quad (\text{Corollary 1401}) \\
 &= (\pi^{\theta})^{-1}(\Delta^{\mathcal{A}^{\theta}}) \quad (\text{Hypothesis}) \\
 &= \theta. \quad (\text{Set Theory})
 \end{aligned}$$

Since, by definition $\tilde{\Omega}^{\mathcal{A}}$ is order preserving and, by Lemma 1444, $\tilde{H}^{\mathcal{A}}$ is also order preserving, we conclude that $\tilde{\Omega}^{\mathcal{A}}$ is an order isomorphism with inverse $\tilde{H}^{\mathcal{A}}$. ■

We show next that the poset of $\mathcal{I}$ -congruence systems on an $\mathbf{F}$ -algebraic system $\mathcal{A}$ is a complete lattice with infimum given by signature-wise intersection. In conjunction with the Isomorphism Theorem, this will yield that the poset of full $\mathcal{I}$ -structures on $\mathcal{A}$ is also a complete lattice.

Theorem 1446 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, the poset $\langle \text{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is a complete lattice with infimum given by signature-wise intersection.*

Proof: First, note that $\nabla^{\mathcal{A}} \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$, since $\tilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\nabla^{\mathcal{A}})) = \Delta^{\mathcal{A}/\nabla^{\mathcal{A}}}$ and, hence, $\mathcal{A}/\nabla^{\mathcal{A}} \in \text{AlgSys}(\mathcal{I})$. So $\text{ConSys}^{\mathcal{I}}(\mathcal{A})$ has a largest element. Assume, next, that, for all $i \in I$, $\theta^i \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. We must show that $\bigcap_{i \in I} \theta^i \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. To this end, set $\theta := \bigcap_{i \in I} \theta^i$ and consider the projection morphisms

$$\langle I, \pi^i \rangle : \mathcal{A}^{\theta} \rightarrow \mathcal{A}^{\theta^i}, \quad i \in I,$$

which are bilogical morphisms

$$\langle I, \pi^i \rangle : \langle \mathcal{A}^{\theta}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta}) \rangle \mapsto \langle \mathcal{A}^{\theta^i}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}) \rangle, \quad i \in I.$$

By hypothesis, $\langle \mathcal{A}^{\theta^i}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}) \rangle$ is reduced, i.e.,

$$\tilde{\Omega}^{\mathcal{A}^{\theta^i}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i})) = \Delta^{\mathcal{A}^{\theta^i}}, \quad i \in I.$$

Now we have, for all $i \in I$,

$$\begin{aligned} \tilde{\Omega}^{\mathcal{A}^{\theta}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta})) &\leq \tilde{\Omega}^{\mathcal{A}^{\theta}}((\pi^i)^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}))) \\ &= (\pi^i)^{-1}(\tilde{\Omega}^{\mathcal{A}^{\theta^i}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta^i}))) \\ &= (\pi^i)^{-1}(\Delta^{\mathcal{A}^{\theta^i}}) \\ &= \theta^i / \theta. \end{aligned}$$

Thus, we get

$$\tilde{\Omega}^{\mathcal{A}^{\theta}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta})) \leq \bigcap_{i \in I} (\theta^i / \theta) = (\bigcap_{i \in I} \theta^i) / \theta = \theta / \theta = \Delta^{\mathcal{A}^{\theta}}.$$

We conclude that $\langle \mathcal{A}^{\theta}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}^{\theta}) \rangle$ is reduced and, hence, $\mathcal{A}^{\theta} \in \text{AlgSys}(\mathcal{I})$, giving that $\theta \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$.

The conclusion of the theorem now follows. ■

As a consequence of the Isomorphism Theorem 1445 and Theorem 1446, we get

Corollary 1447 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is a complete lattice and*

$$\tilde{\Omega}^{\mathcal{A}} : \langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle \rightarrow \langle \text{ConSys}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$$

is a lattice isomorphism.

Proof: By Theorems 1445 and 1446. ■

It follows from the preceding results that, given a collection $\{\mathbb{I}^i : i \in I\} \subseteq \text{FStr}^{\mathcal{I}}(\mathcal{A})$, with $\mathbb{I}^i = \langle \mathcal{A}, D^i \rangle$, $i \in I$, its infimum in $\langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is the $\mathcal{I}$ -structure

$$\langle \mathcal{A}, (\pi^\theta)^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}^\theta)) \rangle,$$

where $\theta = \bigcap_{i \in I} \widetilde{\Omega}^{\mathcal{A}}(\mathbb{I}^i)$, and $\langle I, \pi^\theta \rangle : \mathcal{A} \rightarrow \mathcal{A}^\theta$ is the quotient morphism. It is not necessarily the case, however, that this system be the signature-wise intersection of the $\mathbb{I}^i$'s. In other words, $\langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ is not, in general, a sublattice of the complete lattice of all $\mathcal{I}$ -structures on $\mathcal{A}$.

It turns out that biological morphisms with isomorphic functor components induce isomorphisms between principal ideals of the corresponding full structure lattices and, similarly isomorphisms between principal ideals of the corresponding lattices of congruence systems.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Let also $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, be an $\mathbf{F}$ -algebraic system. Consider the complete lattice $\langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ and let $\mathbb{I} = \langle \mathcal{A}, D \rangle \in \text{FStr}^{\mathcal{I}}(\mathcal{A})$. Recall that the ordering $\leq$ reflects the ordering of the closure operators on $\mathcal{A}$, which is dual to the inclusion ordering of the corresponding closure set systems. So, when we refer to an ideal in $\langle \text{FStr}^{\mathcal{I}}(\mathcal{A}), \leq \rangle$ we mean in the form of closure (operator) families and this translates to a filter, when one views structures in the form of their theory families. Keeping this in mind, we introduce the notation $\text{FStr}^{\mathcal{I}}(\mathbb{I})$ to refer to the principal ideal of all full $\mathcal{I}$ -structures on $\mathcal{A}$ generated by $\mathbb{I}$. These are full $\mathcal{I}$ -structures whose collection of theory families include $\mathcal{D}$.

$$\begin{aligned} \text{FStr}^{\mathcal{I}}(\langle \mathcal{A}, D \rangle) &= \{ \langle \mathcal{A}, D' \rangle \in \text{FStr}^{\mathcal{I}}(\mathcal{A}) : D' \leq D \} \\ &= \{ \langle \mathcal{A}, \mathcal{D}' \rangle \in \text{FStr}^{\mathcal{I}}(\mathcal{A}) : \mathcal{D} \leq \mathcal{D}' \}. \end{aligned}$$

Then we have the following.

Proposition 1448 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Let also $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}, \text{SEN}', N' \rangle$ be N^b -algebraic systems, over the same category of signatures, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ $\mathbf{F}$ -algebraic systems, $\mathbb{I} = \langle \mathcal{A}, D \rangle$, $\mathbb{I}' = \langle \mathcal{A}', D' \rangle$ full $\mathcal{I}$ -structures and $\langle I, \gamma \rangle : \mathbb{I} \vdash \mathbb{I}'$ a biological morphism. Then*

$$\langle \mathcal{A}, \mathcal{X} \rangle \mapsto \langle \mathcal{A}', \gamma(\mathcal{X}) \rangle$$

is an isomorphism from $\text{FStr}^{\mathcal{I}}(\mathbb{I})$ to $\text{FStr}^{\mathcal{I}}(\mathbb{I}')$.

Moreover, the principal ideals of $\text{ConSys}^{\mathcal{I}}(\mathcal{A})$ and of $\text{ConSys}^{\mathcal{I}}(\mathcal{A}')$, generated by $\widetilde{\Omega}^{\mathcal{A}}(\mathbb{I})$ and $\widetilde{\Omega}^{\mathcal{A}'}(\mathbb{I}')$, respectively, are isomorphic.

Proof: By Corollary 1399, the displayed mapping is an isomorphism between $\mathbf{ClFam}(\mathbb{I})$ and $\mathbf{ClFam}(\mathbb{I}')$. Proposition 1429 gives the statement, since

$\langle I, \gamma \rangle$ induces biological morphisms between the corresponding elements in $\text{ClFam}(\mathbb{L})$ and $\text{ClFam}(\mathbb{L}')$. The second statement now follows by applying the Isomorphism Theorem 1445. ■

Corollary 1449 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Let also $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}, \text{SEN}', N' \rangle$ be N^b -algebraic systems, over the same category of signatures, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ $\mathbf{F}$ -algebraic systems and $\langle I, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$ a surjective morphism, such that*

$$\langle I, \gamma \rangle : \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \vdash \langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle$$

is a biological morphism. Then $\langle \mathcal{A}, \mathcal{X} \rangle \mapsto \langle \mathcal{A}', \gamma(\mathcal{X}) \rangle$ is an isomorphism from $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$ to $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A}')$. Moreover, $\mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}) \cong \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}')$.

Proof: This follows by Proposition 1448, since, by Proposition 1427, the $\mathcal{I}$ -structures $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ and $\langle \mathcal{A}', \text{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle$ are the weakest full $\mathcal{I}$ -structures on $\mathcal{A}$ and $\mathcal{A}'$, respectively. The last isomorphism follows by the second statement of Proposition 1448. ■

We close the section by looking at some functors that relate the categories having as objects the structures that we have focused upon and with surjective homomorphism running between them.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. We describe three categories related to $\mathcal{I}$.

- The category $\mathbf{FStr}(\mathcal{I})$:
 - The objects are full $\mathcal{I}$ -structures $\mathbb{L} = \langle \mathcal{A}, D \rangle$;
 - Given objects $\mathbb{L} = \langle \mathcal{A}, D \rangle$ and $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$, a morphism in $\mathbf{FStr}(\mathcal{I})$

$$\langle H, \gamma \rangle : \mathbb{L} \rightarrow \mathbb{L}'$$

is a surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$, which is also a logical morphism $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$.

It is not difficult to verify that these two clauses specify indeed a category, with composition being ordinary composition of morphisms.

- The category $\mathbf{FStr}^*(\mathcal{I})$:

This is the full subcategory of $\mathbf{FStr}(\mathcal{I})$, with objects all full $\mathcal{I}$ -structures.

- The category $\mathbf{AlgSys}(\mathcal{I})$:

- The objects are $\mathcal{I}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$;

- Given objects $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$, a morphism in $\mathbf{AlgSys}(\mathcal{I})$

$$\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$$

is a surjective $\mathbf{F}$ -algebraic system morphism.

It is not difficult in this case either to verify that these two clauses specify indeed a category, with composition being ordinary composition of morphisms.

The following picture gives an overview of the relationships that hold between these categories and will be established shortly. The categories $\mathbf{AlgSys}(\mathcal{I})$ and $\mathbf{FStr}^*(\mathcal{I})$ are isomorphic through an isomorphism

$$\Phi : \mathbf{AlgSys}(\mathcal{I}) \cong \mathbf{FStr}^*(\mathcal{I}),$$

which will be defined in the upcoming Theorem 1450. Moreover, the category $\mathbf{FStr}^*(\mathcal{I})$ is a reflective subcategory of the category $\mathbf{FStr}(\mathcal{I})$, with reflector the reduction functor $*$: $\mathbf{FStr}(\mathcal{I}) \rightarrow \mathbf{FStr}^*(\mathcal{I})$ that will be visited in detail in the last Theorem 1451 of the section.

$$\mathbf{AlgSys}(\mathcal{I}) \begin{array}{c} \xrightarrow{\Phi} \\ \xleftarrow{\Phi^{-1}} \end{array} \mathbf{FStr}^*(\mathcal{I}) \begin{array}{c} \xleftarrow{J} \\ \xrightarrow{*} \end{array} \mathbf{FStr}(\mathcal{I})$$

Theorem 1450 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then the categories $\mathbf{AlgSys}(\mathcal{I})$ and $\mathbf{FStr}^*(\mathcal{I})$ are isomorphic.*

Proof: We define the functor

$$\Phi : \mathbf{AlgSys}(\mathcal{I}) \rightarrow \mathbf{FStr}^*(\mathcal{I})$$

by setting:

- For all $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathbf{AlgSys}(\mathcal{I})$,

$$\Phi(\mathcal{A}) = \langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle;$$

- For all $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$ in $\mathbf{AlgSys}(\mathcal{I})$,

$$\Phi(\langle H, \gamma \rangle) = \langle H, \gamma \rangle : \langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \rightarrow \langle \mathcal{A}', \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}') \rangle.$$

First, observe that, by Proposition 1434, if $\mathcal{A} \in \mathbf{AlgSys}(\mathcal{I})$, then $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$ -structure. So Φ is correctly defined. Moreover, if $\langle \mathcal{A}, D \rangle \in \mathbf{FStr}^*(\mathcal{I})$, then, again by Proposition 1434, $\mathcal{D} = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathcal{A} \in \mathbf{AlgSys}(\mathcal{I})$. Thus, Φ is a bijection on objects.

Finally, by Corollary 55, if $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{A}'$ is a surjective morphism, then, for all $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}')$, $\gamma^{-1}(T') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\Phi(\langle H, \gamma \rangle)$ is a well-defined logical morphism, by Proposition 1395. Since it is clear that Φ is bijective on morphisms as well, we get that $\Phi : \mathbf{AlgSys}(\mathcal{I}) \rightarrow \mathbf{FStr}^*(\mathcal{I})$ is indeed an isomorphism of categories. ■

Finally, for the reflection:

Theorem 1451 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then $\mathbf{FStr}^*(\mathcal{I})$ is a full reflective subcategory of $\mathbf{FStr}(\mathcal{I})$ with reflector the reduction functor $*$: $\mathbf{FStr}(\mathcal{I}) \rightarrow \mathbf{FStr}^*(\mathcal{I})$.*

Proof: It is obvious that $\mathbf{FStr}^*(\mathcal{I})$ is a full subcategory of $\mathbf{FStr}(\mathcal{I})$. We must show that, given $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathbf{FStr}(\mathcal{I})$, the pair $\langle \mathbb{L}^*, \langle I, \pi \rangle : \mathbb{L} \rightarrow \mathbb{L}^* \rangle$ is a reflector, i.e., that, given $\mathbb{L}' = \langle \mathcal{A}', D' \rangle \in \mathbf{FStr}^*(\mathcal{I})$ and $\langle H, \gamma \rangle : \mathbb{L} \rightarrow \mathbb{L}'$ in $\mathbf{FStr}(\mathcal{I})$, there exists a unique $\langle H, \gamma^* \rangle : \mathbb{L}^* \rightarrow \mathbb{L}'$ in $\mathbf{FStr}^*(\mathcal{I})$, such that the following diagram commutes.

$$\begin{array}{ccc} \mathbb{L} & \xrightarrow{\langle H, \gamma \rangle} & \mathbb{L}' \\ & \searrow \langle I, \pi \rangle & \uparrow \langle H, \gamma^* \rangle \\ & & \mathbb{L}^* \end{array}$$

Consider $\mathbb{L}^\gamma := \langle \mathcal{A}, \gamma^{-1}(D') \rangle$. Clearly, since, by hypothesis and Proposition 1395, $\gamma^{-1}(D') \subseteq D$, we have that $\mathbb{L} \leq \mathbb{L}^\gamma$. Now we have

$$\begin{aligned} \text{Ker}(\langle I, \pi \rangle) &= \tilde{\Omega}^{\mathcal{A}}(\mathbb{L}) \quad (\text{Set Theory}) \\ &\leq \tilde{\Omega}^{\mathcal{A}}(\mathbb{L}^\gamma) \quad (\mathbb{L} \leq \mathbb{L}^\gamma) \\ &= \gamma^{-1}(\tilde{\Omega}^{\mathcal{A}'}(\mathbb{L}')) \quad (\text{Corollary 1401}) \\ &= \gamma^{-1}(\Delta^{\mathcal{A}'}) \quad (\mathbb{L}' \in \mathbf{FStr}^*(\mathcal{I})) \\ &= \text{Ker}(\langle H, \gamma \rangle). \quad (\text{Set Theory}) \end{aligned}$$

By the Fill-in Lemma (Proposition 1411), there exists a unique logical morphism $\langle H, \gamma^* \rangle : \mathbb{L}^* \rightarrow \mathbb{L}'$, such that the displayed diagram commutes, which, in addition, is surjective by the commutativity of the triangle. ■

19.8 Frege Relations Revisited

We revisit here in more detail the types of Frege relations and Frege operators one may consider in conjunction with π -institutions or π -structures, more generally.

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system and $T \in \text{SenFam}(\mathbf{A})$.

- The **local Frege relation family** $\lambda^{\mathbf{A}}(T) = \{\lambda_{\Sigma}^{\mathbf{A}}(T)\}_{\Sigma \in |\mathbf{Sign}|}$ of T on $\mathbf{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\lambda_{\Sigma}^{\mathbf{A}}(T) = \{\langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : \phi \in T_{\Sigma} \text{ iff } \psi \in T_{\Sigma}\}.$$

- The **global Frege relation family** $\Lambda^{\mathbf{A}}(T) = \{\Lambda_{\Sigma}^{\mathbf{A}}(T)\}_{\Sigma \in |\mathbf{Sign}|}$ of T on $\mathbf{A}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{aligned} \Lambda_{\Sigma}^{\mathbf{A}}(T) = \{ \langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : & \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma, \Sigma'), \\ & \text{SEN}(f)(\phi) \in T_{\Sigma'} \text{ iff } \text{SEN}(f)(\psi) \in T_{\Sigma'} \}. \end{aligned}$$

The operators $\lambda^{\mathbf{A}}, \Lambda^{\mathbf{A}} : \text{SenFam}(\mathbf{A}) \rightarrow \text{RelFam}(\mathbf{A})$ are called the **local** and **global Frege operators on $\mathbf{A}$** , respectively.

Let now $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ be a π -structure.

- The **local Frege relation family** $\tilde{\lambda}^{\mathbf{A}}(\mathbb{L}) = \tilde{\lambda}^{\mathbf{A}}(D) = \{\tilde{\lambda}_{\Sigma}^{\mathbf{A}}(D)\}_{\Sigma \in |\mathbf{Sign}|}$ of $\mathbb{L}$, or of D on $\mathbf{A}$, is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\tilde{\lambda}_{\Sigma}^{\mathbf{A}}(D) = \{\langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : D_{\Sigma}(\phi) = D_{\Sigma}(\psi)\}.$$

- The **global Frege relation family** $\tilde{\Lambda}^{\mathbf{A}}(\mathbb{L}) = \tilde{\Lambda}^{\mathbf{A}}(D) = \{\tilde{\Lambda}_{\Sigma}^{\mathbf{A}}(D)\}_{\Sigma \in |\mathbf{Sign}|}$ of $\mathbb{L}$, or of D on $\mathbf{A}$, is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{aligned} \tilde{\Lambda}_{\Sigma}^{\mathbf{A}}(D) = \{ \langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : & \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma, \Sigma'), \\ & D_{\Sigma'}(\text{SEN}(f)(\phi)) = D_{\Sigma'}(\text{SEN}(f)(\psi)) \}. \end{aligned}$$

Consider again an algebraic system $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, a π -structure $\mathbb{L} = \langle \mathbf{A}, D \rangle$ and $X \in \text{SenFam}(\mathbf{A})$. Recall the notation $D^X : \mathcal{P}\text{SEN} \rightarrow \mathcal{P}\text{SEN}$ denoting the closure family on $\mathbf{A}$ that is defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \subseteq \text{SEN}(\Sigma)$, by

$$D_{\Sigma}^X(\Phi) = D_{\Sigma}(X_{\Sigma} \cup \Phi).$$

- The **local Frege relation family**

$$\tilde{\lambda}^{\mathbb{L}}(X) = \tilde{\lambda}^{\mathbf{A}, D}(X) = \{\tilde{\lambda}_{\Sigma}^{\mathbf{A}, D}(X)\}_{\Sigma \in |\mathbf{Sign}|}$$

of X in $\mathbb{L}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\tilde{\lambda}_{\Sigma}^{\mathbf{A}, D}(X) = \{\langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : D_{\Sigma}^X(\phi) = D_{\Sigma}^X(\psi)\}.$$

- The **global Frege relation family**

$$\tilde{\Lambda}^{\mathbb{L}}(X) = \tilde{\Lambda}^{\mathbf{A}, D}(X) = \{\tilde{\Lambda}_{\Sigma}^{\mathbf{A}, D}(X)\}_{\Sigma \in |\mathbf{Sign}|}$$

of X in $\mathbb{L}$ is defined by setting, for all $\Sigma \in |\mathbf{Sign}|$,

$$\begin{aligned} \tilde{\Lambda}_{\Sigma}^{\mathbf{A}, D}(X) = \{ \langle \phi, \psi \rangle \in \text{SEN}(\Sigma)^2 : & \text{for all } \Sigma' \in |\mathbf{Sign}|, f \in \mathbf{Sign}(\Sigma, \Sigma'), \\ & D_{\Sigma'}^X(\text{SEN}(f)(\phi)) = D_{\Sigma'}^X(\text{SEN}(f)(\psi)) \}. \end{aligned}$$

The operators $\tilde{\lambda}^{\mathbf{A},D}, \tilde{\Lambda}^{\mathbf{A},D} : \text{SenFam}(\mathbf{A}) \rightarrow \text{RelFam}(\mathbf{A})$ are called the **local** and **global Frege operators on $\mathbb{I}\mathbb{L}$** , respectively.

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathbb{I}\mathbb{L} = \langle \mathbf{A}, D \rangle$ be a π -structure and $X \in \text{SenFam}(\mathbf{A})$. Some obvious relationships hold between several of the notions defined above. We denote by $\text{Thm}(\mathbb{I}\mathbb{L}) = \{\text{Thm}_\Sigma(\mathbb{I}\mathbb{L})\}_{\Sigma \in |\mathbf{Sign}|}$, where $\text{Thm}_\Sigma(\mathbb{I}\mathbb{L}) = D_\Sigma(\emptyset)$, an obvious generalization of the corresponding notion from π -institutions. Note, however, that, since D is not necessarily structural, in this case $\text{Thm}(\mathbb{I}\mathbb{L})$ is a theory family, but not necessarily a theory system. Then, we have the following:

$$\begin{aligned} \tilde{\lambda}^{\mathbf{A}}(D) &= \tilde{\lambda}^{\mathbf{A},D}(\text{Thm}(\mathbb{I}\mathbb{L})); \\ \tilde{\Lambda}^{\mathbf{A}}(D) &= \tilde{\Lambda}^{\mathbf{A},D}(\text{Thm}(\mathbb{I}\mathbb{L})); \\ \tilde{\lambda}^{\mathbf{A},D}(X) &= \bigcap \{ \lambda^{\mathbf{A}}(T) : X \leq T \in \text{ThFam}(\mathbb{I}\mathbb{L}) \}; \\ \tilde{\Lambda}^{\mathbf{A},D}(X) &= \bigcap \{ \Lambda^{\mathbf{A}}(T) : X \leq T \in \text{ThFam}(\mathbb{I}\mathbb{L}) \}. \end{aligned}$$

We show that all three local Frege operators give rise to equivalence families, whereas all three global operators give rise to equivalence systems on the underlying algebraic system $\mathbf{A}$.

Lemma 1452 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, $\mathbb{I}\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure and $X \in \text{SenFam}(\mathbf{A})$.*

- (a) $\lambda^{\mathbf{A}}(X)$, $\tilde{\lambda}^{\mathbf{A}}(D)$ and $\tilde{\lambda}^{\mathbf{A},D}(X)$ are equivalence families on $\mathbf{A}$;
- (b) $\Lambda^{\mathbf{A}}(X)$, $\tilde{\Lambda}^{\mathbf{A}}(D)$ and $\tilde{\Lambda}^{\mathbf{A},D}(X)$ are equivalence systems on $\mathbf{A}$.

Proof: Because of the interdependencies between these concepts, pointed out before the lemma, it suffices to prove the statements only for $\lambda^{\mathbf{A}}(X)$ and $\Lambda^{\mathbf{A}}(X)$. That both $\lambda^{\mathbf{A}}(X)$ and $\Lambda^{\mathbf{A}}(X)$ are equivalence families is obvious because of the properties of the equivalence connective used in their definitions. So it suffices to show only that $\Lambda^{\mathbf{A}}(X)$ is a system, i.e., that it is invariant under signature morphisms. So suppose $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Lambda_\Sigma^{\mathbf{A}}(X)$ and let $\Sigma' \in |\mathbf{Sign}|$ and $f \in \mathbf{Sign}(\Sigma, \Sigma')$.

$$\begin{array}{ccc} \Sigma & \xrightarrow{f} & \Sigma' \\ & \searrow h \quad \swarrow g & \\ & \Sigma'' & \end{array}$$

By the definition of $\Lambda^{\mathbf{A}}(X)$, we have that, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $h \in \mathbf{Sign}(\Sigma, \Sigma'')$,

$$D_{\Sigma''}(\text{SEN}(h)(\phi)) = D_{\Sigma''}(\text{SEN}(h)(\psi)).$$

A fortiori, for all $\Sigma'' \in |\mathbf{Sign}|$ and all $g \in \mathbf{Sign}(\Sigma', \Sigma'')$, we have

$$D_{\Sigma''}(\text{SEN}(g)(\text{SEN}(f)(\phi))) = D_{\Sigma''}(\text{SEN}(g)(\text{SEN}(f)(\psi))).$$

By the definition of $\Lambda^{\mathbf{A}}(X)$, this proves that $\langle \text{SEN}(f)(\phi), \text{SEN}(f)(\psi) \rangle \in \Lambda_{\Sigma'}^{\mathbf{A}}(X)$. Thus $\Lambda^{\mathbf{A}}(X)$ is indeed an equivalence system on $\mathbf{A}$. ■

The next lemma shows that all four “tilde” Frege operators are monotone.

Lemma 1453 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure on $\mathbf{A}$.*

(a) $\tilde{\lambda}^{\mathbf{A}}, \tilde{\Lambda}^{\mathbf{A}} : \mathbf{ClFam}(\mathbf{A}) \rightarrow \mathbf{EqvFam}(\mathbf{A})$ are monotone;

(b) $\tilde{\lambda}^{\mathbf{A},D}, \tilde{\Lambda}^{\mathbf{A},D} : \mathbf{SenFam}(\mathbf{A}) \rightarrow \mathbf{EqvFam}(\mathbf{A})$ are monotone.

Proof: Suppose $D, D' \in \mathbf{ClFam}(\mathbf{A})$, such that $D \leq D'$, and let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \tilde{\lambda}_{\Sigma}^{\mathbf{A}}(D)$. Then $D_{\Sigma}(\phi) = D_{\Sigma}(\psi)$, whence $D'_{\Sigma}(\phi) = D'_{\Sigma}(\psi)$. Thus, $\langle \phi, \psi \rangle \in \tilde{\lambda}_{\Sigma}^{\mathbf{A}}(D')$. We conclude that $\tilde{\lambda}^{\mathbf{A}}(D) \leq \tilde{\lambda}^{\mathbf{A}}(D')$. The proof for $\tilde{\Lambda}^{\mathbf{A}} : \mathbf{ClFam}(\mathbf{A}) \rightarrow \mathbf{EqvFam}(\mathbf{A})$ is similar.

Suppose, next, that $X, X' \in \mathbf{SenFam}(\mathbf{A})$, such that $X \leq X'$. Note that, in this situation, we have

$$\{T \in \text{ThFam}(\mathbb{L}) : X' \leq T\} \subseteq \{T \in \text{ThFam}(\mathbb{L}) : X \leq T\}.$$

Therefore, we have

$$\begin{aligned} \tilde{\lambda}^{\mathbf{A},D}(X) &= \bigcap \{ \lambda^{\mathbf{A}}(T) : X \leq T \in \text{ThFam}(\mathbb{L}) \} \\ &\leq \bigcap \{ \lambda^{\mathbf{A}}(T) : X' \leq T \in \text{ThFam}(\mathbb{L}) \} \\ &= \tilde{\lambda}^{\mathbf{A},D}(X'). \end{aligned}$$

The proof for $\tilde{\Lambda}^{\mathbf{A},D} : \mathbf{SenFam}(\mathbf{A}) \rightarrow \mathbf{EqvFam}(\mathbf{A})$ is similar. ■

The equivalence families produced by applying the six Frege operators form a hierarchy under inclusion that we now make explicit.

Proposition 1454 *Let $\mathbf{A} = \langle \mathbf{A}, \text{SEN}, N \rangle$ be an algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure and $X \in \mathbf{SenFam}(\mathbf{A})$. Then, we have the following inclusions between equivalence families on $\mathbf{A}$:*

Proof: First, note that the three southwest inclusions are obvious, since the conditions defining $\tilde{\lambda}^{\mathbf{A}}$, $\tilde{\lambda}^{\mathbf{A},D}$ and $\lambda^{\mathbf{A}}$ are special cases of the ones defining $\tilde{\Lambda}^{\mathbf{A}}$, $\tilde{\Lambda}^{\mathbf{A},D}$ and $\Lambda^{\mathbf{A}}$, respectively.

We show, next, the southeast inclusions between the λ 's, since the ones between the Λ 's may shown similarly. We have

$$\tilde{\lambda}^{\mathbf{A}}(D) = \tilde{\lambda}^{\mathbf{A},D}(\text{Thm}(\mathbb{L})) \leq \tilde{\lambda}^{\mathbf{A},D}(D(X)) = \tilde{\lambda}^{\mathbf{A},D}(X).$$

Moreover,

$$\begin{aligned} \tilde{\lambda}^{\mathbf{A},D}(X) &= \bigcap \{ \lambda^{\mathbf{A}}(T) : X \leq T \in \text{ThFam}(\mathbb{L}) \} \\ &\leq \lambda^{\mathbf{A}}(D(X)). \end{aligned}$$

Therefore, we have $\tilde{\lambda}^{\mathbf{A}}(D) \leq \tilde{\lambda}^{\mathbf{A},D}(X) \leq \lambda^{\mathbf{A}}(D(X))$. ■

In the case of structural π -structures, i.e., π -institutions, the hierarchy collapses to a smaller one, the top pair collapses and in the case of a sentence system, the middle pair does also. More precisely, we have

Proposition 1455 *Let $\mathbf{A} = \langle \mathbf{A}, \text{SEN}, N \rangle$ be an algebraic system, $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure and $X \in \text{SenSys}(\mathbf{A})$. If D is structural, then*

$$\tilde{\Lambda}^{\mathbf{A}}(D) = \tilde{\lambda}^{\mathbf{A}}(D) \quad \text{and} \quad \tilde{\Lambda}^{\mathbf{A},D}(X) = \tilde{\lambda}^{\mathbf{A},D}(X).$$

Proof: By the remarks preceding Lemma 1452, it suffices to show that the second equation holds. Since it is always the case that $\tilde{\Lambda}^{\mathbf{A},D}(X) \leq \tilde{\lambda}^{\mathbf{A},D}(X)$, we must prove the opposite inclusion. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \tilde{\lambda}^{\mathbf{A},D}(X)$. Then, we have, by definition, $D_{\Sigma}(X_{\Sigma}, \phi) = D_{\Sigma}(X_{\Sigma}, \psi)$. By the structurality of D , for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$D_{\Sigma'}(\text{SEN}(f)(X_{\Sigma}), \text{SEN}(f)(\phi)) = D_{\Sigma'}(\text{SEN}(f)(X_{\Sigma}), \text{SEN}(f)(\psi)).$$

Therefore, if X is a sentence system, we get

$$D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi)) = D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\psi)).$$

We conclude that $\langle \phi, \psi \rangle \in \tilde{\Lambda}^{\mathbf{A},D}(X)$. ■

Thus, if $\mathbb{L} = \langle \mathbf{A}, D \rangle$ is a π -institution, and $X \in \text{SenFam}(\mathbf{A})$, we obtain the simplified hierarchy of Frege relation families shown on the left and, if,

in addition, $X \in \text{SenSys}(\mathbf{A})$, we get the linear hierarchy shown on the right.

We look next at how finitariness of a closure family relates to continuity of Frege operators.

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system. Recall that:

- An $X \in \text{SenFam}(\mathbf{A})$ is called **locally finite** if, for all $\Sigma \in |\mathbf{Sign}|$, X_Σ is finite. We write $Y \leq_{lf} X$ to suggest that Y is a locally finite sentence subfamily of X .
- A collection $\mathcal{X} \subseteq \text{SenFam}(\mathbf{A})$ is said to be **locally directed** if, for every $\Sigma \in |\mathbf{Sign}|$ and finite $\mathcal{Y} \subseteq \mathcal{X}$, there exists $X \in \mathcal{X}$, such that $Y_\Sigma \leq X_\Sigma$, for all $Y \in \mathcal{Y}$.

Let $\mathbb{L} = \langle \mathbf{A}, D \rangle$ be a π -structure based on $\mathbf{A}$.

- $\mathbb{L}$ is **finitary** if, for all $X \in \text{SenFam}(\mathbf{A})$,

$$D(X) = \bigcup \{D(Y) : Y \leq_{lf} X\}.$$

- The operator $\tilde{\lambda}^{\mathbf{A},D} : \text{SenFam}(\mathbf{A}) \rightarrow \text{EqvFam}(\mathbf{A})$ is **locally continuous** if, for every locally directed $\{X^i : i \in I\} \subseteq \text{SenFam}(\mathbf{A})$,

$$\tilde{\lambda}^{\mathbf{A},D}\left(\bigcup_{i \in I} X^i\right) = \bigcup_{i \in I} \tilde{\lambda}^{\mathbf{A},D}(X^i).$$

Proposition 1456 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$. $\mathbb{L}$ is finitary if and only if*

$$\tilde{\lambda}^{\mathbf{A},D} : \text{SenFam}(\mathbf{A}) \rightarrow \text{EqvFam}(\mathbf{A})$$

is locally continuous.

Proof: Suppose, first, that $\mathbb{L}$ is finitary and let $\{X^i : i \in I\} \subseteq \text{SenFam}(\mathbf{A})$ be locally directed. Since, by Lemma 1453, $\tilde{\lambda}^{\mathbf{A},D}$ is monotone, we have

$$\bigcup_{i \in I} \tilde{\lambda}^{\mathbf{A},D}(X^i) \leq \tilde{\lambda}^{\mathbf{A},D}(\bigcup_{i \in I} X^i).$$

To show the reverse inclusion, let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \tilde{\lambda}_{\Sigma}^{\mathbf{A},D}(\bigcup_{i \in I} X^i)$. Then, by definition, $D_{\Sigma}(\bigcup_{i \in I} X_{\Sigma}^i, \phi) = D_{\Sigma}(\bigcup_{i \in I} X_{\Sigma}^i, \psi)$. Since $\mathbb{L}$ is finitary, there exists finite $\Phi \leq_f \bigcup_{i \in I} X_{\Sigma}^i$, such that $D_{\Sigma}(\Phi, \phi) = D_{\Sigma}(\Phi, \psi)$. Hence, since $\{X^i : i \in I\}$ is locally directed, there exists $i \in I$, such that $\Phi \subseteq X_{\Sigma}^i$. Hence, $D_{\Sigma}(X_{\Sigma}^i, \phi) = D_{\Sigma}(X_{\Sigma}^i, \psi)$, i.e., $\langle \phi, \psi \rangle \in \tilde{\lambda}_{\Sigma}^{\mathbf{A},D}(X^i)$. We conclude that $\tilde{\lambda}^{\mathbf{A},D}(\bigcup_{i \in I} X^i) \leq \bigcup_{i \in I} \tilde{\lambda}^{\mathbf{A},D}(X^i)$.

Assume, conversely, that $\tilde{\lambda}^{\mathbf{A},D}$ is locally continuous and consider $X \in \text{SenFam}(\mathbf{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$, such that $\phi \in D_{\Sigma}(X_{\Sigma})$. Let $\mathcal{Z} = \{Z \in \text{SenFam}(\mathbf{A}) : Z \leq_{lf} X\}$. $\mathcal{Z}$ is a locally directed family, such that $\bigcup \mathcal{Z} = X$. For all $\psi \in X_{\Sigma}$, we have $D_{\Sigma}(X_{\Sigma}, \phi) = D_{\Sigma}(X_{\Sigma}, \psi) = D_{\Sigma}(X_{\Sigma})$. So we get

$$\langle \phi, \psi \rangle \in \tilde{\lambda}_{\Sigma}^{\mathbf{A},D}(X) = \tilde{\lambda}_{\Sigma}^{\mathbf{A},D}(\bigcup \mathcal{Z}).$$

By the local directedness of $\mathcal{Z}$ and local continuity of $\tilde{\lambda}^{\mathbf{A},D}$, we get $\langle \phi, \psi \rangle \in \bigcup_{Z \in \mathcal{Z}} \tilde{\lambda}_{\Sigma}^{\mathbf{A},D}(Z)$. Therefore, we get, for some $Z \leq_{lf} X$, $\phi \in D_{\Sigma}(Z_{\Sigma}, \psi) = D_{\Sigma}(Z_{\Sigma})$. This shows that $\mathbb{L}$ is finitary. $\blacksquare$

Among the key properties of Frege relations, which partly explains their usefulness in the algebraic study of logical systems, is that, loosely speaking, they are approximated from below by the Leibniz, the Tarski and the Suszko congruence systems.

Proposition 1457 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$ and $T \in \text{ThFam}(\mathbb{L})$.*

- (a) *The Leibniz congruence system $\Omega^{\mathbf{A}}(T)$ is the largest congruence system on $\mathbf{A}$ included in $\Lambda^{\mathbf{A}}(T)$ and in $\lambda^{\mathbf{A}}(T)$;*
- (b) *The Tarski congruence system $\tilde{\Omega}^{\mathbf{A}}(D)$ is the largest congruence system on $\mathbf{A}$ included in $\tilde{\Lambda}^{\mathbf{A}}(D)$ and in $\tilde{\lambda}^{\mathbf{A}}(D)$;*
- (c) *The Suszko congruence system $\tilde{\Omega}^{\mathbf{A},D}(T)$ is the largest congruence system on $\mathbf{A}$ included in $\tilde{\Lambda}^{\mathbf{A},D}(T)$ and in $\tilde{\lambda}^{\mathbf{A},D}(T)$.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\mathbf{A}}(T)$. Since $\Omega^{\mathbf{A}}(T)$ is a congruence system, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $\langle \text{SEN}(f)(\phi), \text{SEN}(f)(\psi) \rangle \in \Omega_{\Sigma'}^{\mathbf{A}}(T)$. Thus, by the compatibility property of $\Omega^{\mathbf{A}}(T)$ with T , we get

$$\text{SEN}(f)(\phi) \in T_{\Sigma'} \quad \text{iff} \quad \text{SEN}(f)(\psi) \in T_{\Sigma'},$$

i.e., $\langle \phi, \psi \rangle \in \Lambda_{\Sigma}^{\mathbf{A}}(T)$. We conclude that $\Omega^{\mathbf{A}}(T) \leq \Lambda^{\mathbf{A}}(T) \leq \lambda^{\mathbf{A}}(T)$.

Suppose, next, that $\theta \in \text{ConSys}(\mathbf{A})$, such that $\theta \leq \lambda^{\mathbf{A}}(T)$. If $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \theta_\Sigma$ and $\phi \in T_\Sigma$, then $\langle \phi, \psi \rangle \in \lambda^{\mathbf{A}}(T)$ and $\phi \in T_\Sigma$, whence by the definition of $\lambda^{\mathbf{A}}(T)$, $\psi \in T_\Sigma$. Thus, θ is a congruence system on $\mathbf{A}$ compatible with T and, therefore, $\theta \leq \Omega^{\mathbf{A}}(T)$, by the maximality property of $\Omega^{\mathbf{A}}(T)$.

Parts (b) and (c) can be proved similarly. $\blacksquare$

We show next that Frege relations are preserved under inverse surjective morphisms.

Lemma 1458 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be algebraic systems, $\mathbb{I} = \langle \mathbf{A}, D \rangle$, $\mathbb{I}' = \langle \mathbf{A}', D' \rangle$ be π -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbf{A} \rightarrow \mathbf{A}'$ a surjective morphism.*

- (a) *For every $X \in \text{SenFam}(\mathbf{A}')$, $\Lambda^{\mathbf{A}}(\alpha^{-1}(X)) = \alpha^{-1}(\Lambda^{\mathbf{A}'}(X))$ and, also, $\lambda^{\mathbf{A}}(\alpha^{-1}(X)) = \alpha^{-1}(\lambda^{\mathbf{A}'}(X))$;*
- (b) *If $\langle F, \alpha \rangle : \mathbb{I} \vdash \mathbb{I}'$ is a biological morphism, then $\tilde{\Lambda}^{\mathbf{A}}(D) = \alpha^{-1}(\tilde{\Lambda}^{\mathbf{A}'}(D'))$ and, also, $\tilde{\lambda}^{\mathbf{A}}(D) = \alpha^{-1}(\tilde{\lambda}^{\mathbf{A}'}(D'))$.*

Proof:

- (a) Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \text{SEN}(\Sigma)$. We have $\langle \phi, \psi \rangle \in \alpha_\Sigma^{-1}(\Lambda^{\mathbf{A}'}(X))$ iff $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Lambda_{F(\Sigma)}^{\mathbf{A}'}(X)$ iff, by surjectivity, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\text{SEN}'(F(f))(\alpha_\Sigma(\phi)) \in X_{F(\Sigma')} \quad \text{iff} \quad \text{SEN}'(F(f))(\alpha_\Sigma(\psi)) \in X_{F(\Sigma')},$$

iff, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\alpha_{\Sigma'}(\text{SEN}(f)(\phi)) \in X_{F(\Sigma')} \quad \text{iff} \quad \alpha_{\Sigma'}(\text{SEN}'(f)(\psi)) \in X_{F(\Sigma')},$$

iff, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\text{SEN}(f)(\phi) \in \alpha_{\Sigma'}^{-1}(X_{F(\Sigma')}) \quad \text{iff} \quad \text{SEN}(f)(\psi) \in \alpha_{\Sigma'}^{-1}(X_{F(\Sigma')}),$$

iff, $\langle \phi, \psi \rangle \in \Lambda_\Sigma^{\mathbf{A}}(\alpha^{-1}(X))$.

The proof of $\lambda^{\mathbf{A}}(\alpha^{-1}(X)) = \alpha^{-1}(\lambda^{\mathbf{A}'}(X))$ is similar.

- (b) We have

$$\begin{aligned} \tilde{\Lambda}(D) &= \bigcap \{ \Lambda^{\mathbf{A}}(T) : T \in \text{ThFam}(\mathbb{I}) \} \\ &= \bigcap \{ \Lambda(\alpha^{-1}(T')) : T' \in \text{ThFam}(\mathbb{I}') \} \\ &= \bigcap \{ \alpha^{-1}(\Lambda^{\mathbf{A}'}(T')) : T' \in \text{ThFam}(\mathbb{I}') \} \\ &= \alpha^{-1}(\bigcap \{ \Lambda^{\mathbf{A}'}(T') : T' \in \text{ThFam}(\mathbb{I}') \}) \\ &= \alpha^{-1}(\tilde{\Lambda}^{\mathbf{A}'}(D')). \end{aligned}$$

The proof of $\tilde{\lambda}^{\mathbf{A}}(D) = \alpha^{-1}(\tilde{\lambda}^{\mathbf{A}'}(D'))$ is similar. $\blacksquare$

19.9 Fullness and Metalogical Properties

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system.

An **F-rule** is a pair $\langle P, \rho \rangle$, with $P \cup \{\rho\} : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a finite set of natural transformations in N^b .

A **generalized** or **Gentzen F-rule**, or **F-grule** for short, is a pair

$$\langle \{ \langle P^i, \rho^i \rangle : i \in I \}, \langle P, \rho \rangle \rangle,$$

where $\{ \langle P^i, \rho^i \rangle : i \in I \} \cup \{ \langle P, \rho \rangle \}$ is a finite set of **F-rules**. We sometimes write an **F-grule** in the “two-line” format

$$\frac{\langle P^i, \rho^i \rangle : i \in I}{\langle P, \rho \rangle} \quad \text{or} \quad \frac{P^i \vdash \rho^i : i \in I}{P \vdash \rho}.$$

Let $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. $\mathcal{I}$ **satisfies** $\frac{\langle P^i, \rho^i \rangle : i \in I}{\langle P, \rho \rangle}$ if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma)$,

$$\rho_\Sigma^i(\vec{\chi}) \in C_\Sigma(P_\Sigma^i(\vec{\chi})), \quad i \in I, \quad \text{impies} \quad \rho_\Sigma(\vec{\chi}) \in C_\Sigma(P_\Sigma(\vec{\chi})).$$

Similarly, an **F-structure** $\mathbb{L} = \langle \mathcal{A}, D \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, **satisfies** $\frac{\langle P^i, \rho^i \rangle : i \in I}{\langle P, \rho \rangle}$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\chi} \in \mathbf{SEN}(\Sigma)$,

$$\rho_\Sigma^i(\vec{\chi}) \in D_\Sigma(P_\Sigma^i(\vec{\chi})), \quad i \in I, \quad \text{impies} \quad \rho_\Sigma(\vec{\chi}) \in D_\Sigma(P_\Sigma(\vec{\chi})).$$

Since an **F-rule** can be perceived as a special case of an **F-grule** (with empty set of premises), this notion of satisfaction applies in particular to **F-rules**.

It turns out that satisfaction of **F-rules** is transferred from a π -institution to all its structure models.

Proposition 1459 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ satisfies an **F-rule** $\langle P, \rho \rangle$, then every $\mathcal{I}$ -structure satisfies the same **F-rule**.*

Proof: Suppose $\mathcal{I}$ satisfies $\langle P, \rho \rangle$ and let $\mathbb{L} = \langle \mathcal{A}, D \rangle$ be an $\mathcal{I}$ -structure, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$. Then, for all $T \in \text{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma)$, we have $P_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)}$ if and only if $\alpha_\Sigma(P_\Sigma(\vec{\chi})) \subseteq T_{F(\Sigma)}$ if and only if $P_\Sigma(\vec{\chi}) \subseteq \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Thus, since, by Lemma 51, $\alpha^{-1}(T) \in \text{ThFam}(\mathcal{I})$, we get, by hypothesis, $\rho_\Sigma(\vec{\chi}) \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. This is equivalent to $\alpha_\Sigma(\rho_\Sigma(\vec{\chi})) \in T_{F(\Sigma)}$ and, in turn, to $\rho_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in T_{F(\Sigma)}$. We conclude, by the surjectivity of $\langle F, \alpha \rangle$, that $\mathbb{L}$ satisfies $\langle P, \rho \rangle$ as well. $\blacksquare$

Moreover, it turns out that satisfaction of an **F-grule**, in general, is preserved by biological morphisms.

Proposition 1460 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ N^b -algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ π -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism. Then $\mathbb{L}$ satisfies an $\mathbf{F}$ -grule $\langle \{ \langle P^i, \rho^i \rangle : i \in I \}, \langle P, \rho \rangle \rangle$ if and only if $\mathbb{L}'$ satisfies the same $\mathbf{F}$ -grule.*

Proof: Suppose, first, that $\mathbb{L}$ satisfies the $\mathbf{F}$ -grule and let $\Sigma \in |\mathbf{Sign}|$, $\vec{\chi} \in \mathbf{SEN}(\Sigma)$, such that, for all $i \in I$,

$$\rho_{F(\Sigma)}^i(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P_{F(\Sigma)}^i(\alpha_\Sigma(\vec{\chi}))).$$

This is equivalent to

$$\alpha_\Sigma(\rho_\Sigma^i(\vec{\chi})) \in D'_{F(\Sigma)}(\alpha_\Sigma(P_{F(\Sigma)}^i(\vec{\chi}))).$$

Since $\langle F, \alpha \rangle$ is a biological morphism, we get $\rho_\Sigma^i(\vec{\chi}) \in D_\Sigma(P_\Sigma^i(\vec{\chi}))$. Since, by hypothesis, $\mathbb{L}$ satisfies the given $\mathbf{F}$ -grule, we get that $\rho_\Sigma(\vec{\chi}) \in D_\Sigma(P_\Sigma(\vec{\chi}))$. Reversing the steps above, we conclude that

$$\rho'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi}))).$$

Since $\langle F, \alpha \rangle$ is surjective, this shows that $\mathbb{L}'$ satisfies the $\mathbf{F}$ -grule as well.

Suppose, conversely, that $\mathbb{L}'$ satisfies the $\mathbf{F}$ -grule $\langle \{ \langle P^i, \rho^i \rangle : i \in I \}, \langle P, \rho \rangle \rangle$. Let $\Sigma \in |\mathbf{Sign}|$ and $\vec{\chi} \in \mathbf{SEN}(\Sigma)$, such that, for all $i \in I$,

$$\rho_\Sigma^i(\vec{\chi}) \in D_\Sigma(P_\Sigma^i(\vec{\chi})).$$

Since, $\langle F, \alpha \rangle$ is a biological morphism, we get

$$\alpha_\Sigma(\rho_\Sigma^i(\vec{\chi})) \in D'_{F(\Sigma)}(\alpha_\Sigma(P_\Sigma^i(\vec{\chi}))),$$

which gives $\rho_{F(\Sigma)}^i(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P_{F(\Sigma)}^i(\alpha_\Sigma(\vec{\chi})))$. Since, by hypothesis, $\mathbb{L}'$ satisfies the given $\mathbf{F}$ -grule, we now get

$$\rho'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi})) \in D'_{F(\Sigma)}(P'_{F(\Sigma)}(\alpha_\Sigma(\vec{\chi}))).$$

Reversing again the preceding steps, we finally obtain that

$$\rho_\Sigma(\vec{\chi}) \in D_\Sigma(P_\Sigma(\vec{\chi})).$$

Thus, $\mathbb{L}$ satisfies the same $\mathbf{F}$ -grule as well. ■

19.9.1 The Congruence Property

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure.

- $\mathbb{L}$ has the **Congruence Property** if $\tilde{\Lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}$, i.e., by Proposition 1457, if and only if

$$\tilde{\Lambda}^{\mathbf{A}}(D) = \tilde{\Omega}^{\mathbf{A}}(D);$$

- $\mathbb{L}$ has the **strong Congruence Property** if $\tilde{\lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}$, i.e., by Proposition 1457, if and only if

$$\tilde{\lambda}^{\mathbf{A}}(D) = \tilde{\Omega}^{\mathbf{A}}(D).$$

Of course, the strong Congruence Property implies the Congruence Property.

Proposition 1461 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure. If $\mathcal{I}$ has the strong Congruence Property, then it has the Congruence Property.*

Proof: We know that $\tilde{\Omega}^{\mathbf{A}}(D) \leq \tilde{\Lambda}^{\mathbf{A}}(T) \leq \tilde{\lambda}^{\mathbf{A}}(T)$. If $\mathbb{L}$ has the strong Congruence Property, $\tilde{\Omega}^{\mathbf{A}}(D) = \tilde{\lambda}^{\mathbf{A}}(T)$, whence, also, $\tilde{\Omega}^{\mathbf{A}}(D) = \tilde{\Lambda}^{\mathbf{A}}(T)$. Thus, $\mathbb{L}$ has the Congruence Property. ■

Corollary 1462 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a reduced π -structure based on $\mathbf{A}$.*

- (a) $\mathbb{L}$ has the Congruence Property if and only if $\tilde{\Lambda}^{\mathbf{A}}(D) = \Delta^{\mathbf{A}}$.
- (b) $\mathbb{L}$ has the strong Congruence Property if and only if $\tilde{\lambda}^{\mathbf{A}}(D) = \Delta^{\mathbf{A}}$.

Proof: $\mathbb{L}$ has the Congruence Property if and only if $\tilde{\Lambda}^{\mathbf{A}}(D) = \tilde{\Omega}^{\mathbf{A}}(D)$ if and only if, since $\mathbb{L}$ is reduced, $\tilde{\Lambda}^{\mathbf{A}}(D) = \Delta^{\mathbf{A}}$. Part (b) is similar. ■

It turns out that the Congruence Property is preserved in both directions under biological morphisms.

Proposition 1463 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ be algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ π -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism.*

- (a) $\mathbb{L}$ has the Congruence Property if and only if $\mathbb{L}'$ has the Congruence Property;
- (b) $\mathbb{L}$ has the strong Congruence Property if and only if $\mathbb{L}'$ has the strong Congruence Property.

Proof:

(a) We have

$$\begin{aligned}\tilde{\Lambda}^{\mathbf{A}}(D) = \tilde{\Omega}^{\mathbf{A}}(D) & \text{ iff } \alpha^{-1}(\tilde{\Lambda}^{\mathbf{A}'}(D')) = \alpha^{-1}(\tilde{\Omega}^{\mathbf{A}'}(D')) \\ & \text{ iff } \tilde{\Lambda}^{\mathbf{A}'}(D') = \tilde{\Omega}^{\mathbf{A}'}(D'),\end{aligned}$$

the first equivalence by Corollary 1401 and Lemma 1458, and the second equivalence by the surjectivity of $\langle F, \alpha \rangle$. Therefore, $\mathbb{I}\mathbb{L}$ has the Congruence Property if and only if $\mathbb{I}\mathbb{L}'$ has the Congruence Property.

(b) Similarly,

$$\begin{aligned}\tilde{\lambda}^{\mathbf{A}}(D) = \tilde{\omega}^{\mathbf{A}}(D) & \text{ iff } \alpha^{-1}(\tilde{\lambda}^{\mathbf{A}'}(D')) = \alpha^{-1}(\tilde{\omega}^{\mathbf{A}'}(D')) \\ & \text{ iff } \tilde{\lambda}^{\mathbf{A}'}(D') = \tilde{\omega}^{\mathbf{A}'}(D'),\end{aligned}$$

the first equivalence by Corollary 1401 and Lemma 1458, and the second equivalence by the surjectivity of $\langle F, \alpha \rangle$. Therefore, $\mathbb{I}\mathbb{L}$ has the strong Congruence Property if and only if $\mathbb{I}\mathbb{L}'$ has the strong Congruence Property. ■

Using the Congruence Property, we are now able to introduce the first two classes of the Frege hierarchy of π -institutions, which will be looked more closely at in a subsequent chapter.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, \mathbf{N}^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.

- $\mathcal{I}$ is **selfextensional** if it has the Congruence Property, i.e., if

$$\tilde{\Lambda}(\mathcal{I}) = \tilde{\Omega}(\mathcal{I}).$$

Recall from Proposition 1455, that, since $\mathcal{I}$, is structural, this is equivalent to having the strong Congruence Property.

- $\mathcal{I}$ is **fully selfextensional** if every full $\mathcal{I}$ -structure $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle$ has the Congruence Property, i.e., if, for all $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle \in \mathbf{FStr}(\mathcal{I})$,

$$\tilde{\Lambda}^{\mathcal{A}}(D) = \tilde{\Omega}^{\mathcal{A}}(D).$$

Recall, also, from Proposition 1426 and Proposition 1455, that, since every full $\mathcal{I}$ -structure is structural, this amounts to every full $\mathcal{I}$ -structure having the strong Congruence Property.

We give a characterization of selfextensional π -institutions next.

Proposition 1464 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, \mathbf{N}^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is selfextensional if and only if, for all $\sigma^b : (\mathbf{SEN}^b)^k \rightarrow \mathbf{SEN}^b$ in $\mathbf{N}^b$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_i, \psi_i \in \mathbf{SEN}^b(\Sigma)$, $i < k$,*

$$\begin{aligned}C_{\Sigma}(\phi_i) &= C_{\Sigma}(\psi_i), \quad i < k, \\ \text{imply } C_{\Sigma}(\sigma_{\Sigma}^b(\phi_0, \dots, \phi_{k-1})) &= C_{\Sigma}(\sigma_{\Sigma}^b(\psi_0, \dots, \psi_{k-1})).\end{aligned}$$

Proof: Suppose that $\mathcal{I}$ is selfextensional and let $\sigma^b \in N^b$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi_i, \psi_i \in \text{SEN}^b(\Sigma)$, $i < k$, such that $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$, $i < k$. Thus, for all $i < k$, $\langle \phi_i, \psi_i \rangle \in \tilde{\lambda}_\Sigma(\mathcal{I}) = \tilde{\Omega}_\Sigma(\mathcal{I})$, by selfextensionality. Since $\tilde{\Omega}(\mathcal{I})$ is a congruence system,

$$\langle \sigma_\Sigma^b(\phi_0, \dots, \phi_{k-1}), \sigma_\Sigma^b(\psi_0, \dots, \psi_{k-1}) \rangle \in \tilde{\Omega}_\Sigma(\mathcal{I}) = \tilde{\lambda}_\Sigma(\mathcal{I}).$$

We conclude that $C_\Sigma(\sigma_\Sigma^b(\phi_0, \dots, \phi_{k-1})) = C_\Sigma(\sigma_\Sigma^b(\psi_0, \dots, \psi_{k-1}))$.

Suppose, conversely, that the displayed condition holds. Then $\tilde{\lambda}(\mathcal{I})$ is a congruence system on $\mathbf{F}$. Therefore, by Proposition 1457, we have that $\tilde{\Omega}(\mathcal{I}) = \tilde{\lambda}(\mathcal{I})$. We conclude that $\mathcal{I}$ is selfextensional. $\blacksquare$

And also a characterization of fully selfextensional π -institutions.

Proposition 1465 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is fully selfextensional if and only if every $\mathbf{F}$ -structure of the form $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ has the Congruence Property.*

Proof: Assume, first, that $\mathcal{I}$ is fully selfextensional. By definition, every full $\mathcal{I}$ -structure has the Congruence Property. By Proposition 1427, $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ is full, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$. Therefore, every $\mathbf{F}$ -structure of the form $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ has the Congruence Property.

Assume, conversely, that every $\mathbf{F}$ -structure of the form $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ has the Congruence Property. Let $\mathbb{L} = \langle \mathcal{A}, D \rangle$ be a full $\mathcal{I}$ -structure. Then, by definition, the reduction morphism is a biological morphism

$$\langle I, \pi \rangle : \langle \mathcal{A}, D \rangle \mapsto \langle \mathcal{A}^*, \text{FiFam}^\mathcal{I}(\mathcal{A}^*) \rangle.$$

By hypothesis, $\langle \mathcal{A}^*, \text{FiFam}^\mathcal{I}(\mathcal{A}^*) \rangle$ has the Congruence Property. Thus, by Proposition 1463, $\mathbb{L}$ also has the Congruence Property. Therefore, every full $\mathcal{I}$ -structure has the Congruence Property and we conclude that $\mathcal{I}$ is fully selfextensional. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Recall that the **Lindenbaum-Tarski algebraic system of $\mathcal{I}$** is the algebraic system $\mathcal{F}/\tilde{\Omega}(\mathcal{I})$, where $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. Recall, also, that, given a class of $\mathbf{F}$ -algebraic systems, $\mathbf{Q}(\mathbf{K})$ denotes the syntactic variety generated by $\mathbf{K}$, i.e., those $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, such that $\bigcap \{ \text{Ker}(\mathcal{K}) : \mathcal{K} \in \mathbf{K} \} \leq \text{Ker}(\mathcal{A})$. We denoted $\mathbf{Q}(\mathcal{I}) = \mathbf{Q}(\mathcal{F}/\tilde{\Omega}(\mathcal{I}))$, the syntactic variety generated by the Lindenbaum-Tarski $\mathbf{F}$ -algebraic system of $\mathcal{I}$. Moreover, given $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, we write $\mathbf{K} \models_\Sigma \phi \approx \psi$ for $\langle \phi, \psi \rangle \in \bigcap_{\mathcal{K} \in \mathbf{K}} \text{Ker}_\Sigma(\mathcal{K})$.

Using these conventions, we can formulate a proposition to the effect that, for a selfextensional π -institution $\mathcal{I}$, an equation is satisfied in $\mathbf{Q}(\mathcal{I})$ if and only if it is in the Frege equivalence family $\tilde{\lambda}(\mathcal{I})$.

Proposition 1466 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is selfextensional, then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,*

$$\mathbf{Q}(\mathcal{I}) \models_{\Sigma} \phi \approx \psi \quad \text{if and only if} \quad \langle \phi, \psi \rangle \in \widetilde{\lambda}_{\Sigma}(\mathcal{I}).$$

Proof: By the definition of $\mathbf{Q}(\mathcal{I})$, it is easy to see that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\mathbf{Q}(\mathcal{I}) \models_{\Sigma} \phi \approx \psi \quad \text{iff} \quad \langle \phi, \psi \rangle \in \widetilde{\Omega}_{\Sigma}(\mathcal{I}).$$

Since $\mathcal{I}$ is assumed selfextensional, this happens if and only if $\langle \phi, \psi \rangle \in \widetilde{\Lambda}_{\Sigma}(\mathcal{I})$, i.e., due to the structurality of C , if and only if $\langle \phi, \psi \rangle \in \widetilde{\lambda}_{\Sigma}(\mathcal{I})$. ■

19.9.2 The Property of Conjunction

Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system, such that, in N , there exists a binary natural transformation

$$\wedge : \mathbf{SEN}^2 \rightarrow \mathbf{SEN},$$

and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure. We say that $\mathbb{L}$ has the **Conjunction Property with respect to $\wedge$** if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathbf{SEN}(\Sigma)$,

$$D_{\Sigma}(\phi \wedge_{\Sigma} \psi) = D_{\Sigma}(\phi, \psi),$$

where $\phi \wedge_{\Sigma} \psi := \wedge_{\Sigma}(\phi, \psi)$. In this case, we also say $\wedge$ is a **conjunction** for $\mathbb{L}$ and that $\mathbb{L}$ is **conjunctive**.

Lemma 1467 *Let $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$ be an algebraic system, with $\wedge : \mathbf{SEN}^2 \rightarrow \mathbf{SEN}$ in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$. $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$ if and only if, for every $T \in \mathbf{ThFam}(\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathbf{SEN}(\Sigma)$,*

$$\phi \wedge_{\Sigma} \psi \in T_{\Sigma} \quad \text{iff} \quad \phi \in T_{\Sigma} \text{ and } \psi \in T_{\Sigma}.$$

Proof: Suppose that $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$ and let $T \in \mathbf{ThFam}(\mathbb{L})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi \in \mathbf{SEN}(\Sigma)$.

If $\phi \wedge_{\Sigma} \psi \in T_{\Sigma}$, then

$$\phi \in D_{\Sigma}(\phi, \psi) = D_{\Sigma}(\phi \wedge_{\Sigma} \psi) \subseteq D_{\Sigma}(T_{\Sigma}) = T_{\Sigma}.$$

Similarly, $\psi \in T_{\Sigma}$.

Conversely, if $\phi, \psi \in T_{\Sigma}$, then

$$\phi \wedge_{\Sigma} \psi \in D_{\Sigma}(\phi \wedge_{\Sigma} \psi) = D_{\Sigma}(\phi, \psi) \subseteq D_{\Sigma}(T_{\Sigma}) = T_{\Sigma}.$$

Thus, $\phi \wedge_{\Sigma} \psi \in T_{\Sigma}$ if and only if $\phi, \psi \in T_{\Sigma}$.

Suppose, conversely, that the displayed condition in the statement is satisfied. Then, for all $\Sigma \in |\mathbf{Sign}|$, and all $\phi, \psi \in \text{SEN}(\Sigma)$,

$$\begin{aligned} D_{\Sigma}(\phi \wedge_{\Sigma} \psi) &= \bigcap \{T_{\Sigma} : T \in \text{ThFam}(\mathbb{L}) \text{ and } \phi \wedge_{\Sigma} \psi \in T_{\Sigma}\} \\ &= \bigcap \{T_{\Sigma} : T \in \text{Thfam}(\mathbb{L}) \text{ and } \phi, \psi \in T_{\Sigma}\} \\ &= D_{\Sigma}(\phi, \psi). \end{aligned}$$

So $\wedge : \text{SEN}^2 \rightarrow \text{SEN}$ is a conjunction for $\mathbb{L}$. ■

In terms of **F**-rules one can characterize the Conjunction Property as follows.

Proposition 1468 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\wedge^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$. $\mathcal{I}$ has the Conjunction Property if and only if it satisfies*

$$p^{2,0}, p^{2,1} \vdash \wedge^b \circ \langle p^{2,0}, p^{2,1} \rangle, \quad \wedge^b \circ \langle p^{2,0}, p^{2,1} \rangle \vdash p^{2,0}, \quad \wedge^b \circ \langle p^{2,0}, p^{2,1} \rangle \vdash p^{2,1}.$$

Note that, in practice, we write these **F**-grules in the more familiar form

$$x, y \vdash x \wedge^b y, \quad x \wedge^b y \vdash x, \quad x \wedge^b y \vdash y,$$

where $x, y, z, \dots$ stand for the corresponding projection natural transformations in N^b .

Proof: We have that $\mathcal{I}$ satisfies

$$x, y \vdash x \wedge^b y, \quad x \wedge^b y \vdash x, \quad x \wedge^b y \vdash y,$$

iff, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$\phi \wedge_{\Sigma}^b \psi \in C_{\Sigma}(\phi, \psi), \quad \phi \in C_{\Sigma}(\phi \wedge_{\Sigma}^b \psi), \quad \psi \in C_{\Sigma}(\phi \wedge_{\Sigma}^b \psi),$$

iff, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$C_{\Sigma}(\phi \wedge_{\Sigma}^b \psi) = C_{\Sigma}(\phi, \psi)$$

iff $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^b$. ■

Having the Conjunction Property is preserved under biological morphisms in both directions.

Proposition 1469 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system with a binary $\wedge^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b . Suppose $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ are N^b -algebraic systems $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ π -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism. $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$ if and only if $\mathbb{L}'$ has the Conjunction Property with respect to $\wedge'$.*

Proof: This follows by Proposition 1468 and Proposition 1460. $\blacksquare$

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system and $\wedge : \text{SEN}^2 \rightarrow \text{SEN}$ a binary natural transformation in N . We denote by $N^\wedge$ the category of natural transformations on SEN generated by $\wedge$. Clearly, since $\wedge$ is in N , we have that $N^\wedge$ is a wide subcategory of N . Moreover, we denote

$$\mathbf{A}^\wedge = \langle \mathbf{Sign}, \text{SEN}, N^\wedge \rangle$$

the algebraic system that results by taking $N^\wedge$ instead of N as its category of natural transformations. This corresponds to the well-known operation of reducing the type of an algebra.

Proposition 1470 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\wedge : \text{SEN}^2 \rightarrow \text{SEN}$ in N , and $\mathbb{I}\mathbf{L} = \langle \mathbf{A}, D \rangle$ be a π -structure based on $\mathbf{A}$. If $\mathbb{I}\mathbf{L}$ has the Conjunction Property with respect to $\wedge$, then $\tilde{\Lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}^\wedge$. Moreover, for all $X \in \text{SenFam}(\mathbf{A})$, $\tilde{\Lambda}^{\mathbf{A}, D}(X)$ is also a congruence system on $\mathbf{A}^\wedge$.*

Proof: It suffices to show that, for all $T \in \text{ThFam}(\mathbb{I}\mathbf{L})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \phi', \psi, \psi' \in \text{SEN}(\Sigma)$,

$$\langle \phi, \phi' \rangle, \langle \psi, \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}}(T) \quad \text{implies} \quad \langle \phi \wedge_\Sigma \psi, \phi' \wedge_\Sigma \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}}(T).$$

To this end, suppose $\Sigma \in |\mathbf{Sign}|$, $\phi, \phi', \psi, \psi' \in \text{SEN}(\Sigma)$, such that $\langle \phi, \phi' \rangle, \langle \psi, \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}}(T)$. Then, by definition, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\begin{aligned} \text{SEN}(f)(\phi) \in T_{\Sigma'} & \quad \text{iff} \quad \text{SEN}(f)(\phi') \in T_{\Sigma'}, \\ \text{SEN}(f)(\psi) \in T_{\Sigma'} & \quad \text{iff} \quad \text{SEN}(f)(\psi') \in T_{\Sigma'}. \end{aligned}$$

Thus, we have, by the Conjunction Property and Lemma 1467,

$$\begin{aligned} \text{SEN}(f)(\phi \wedge_\Sigma \psi) \in T_{\Sigma'} & \quad \text{iff} \quad \text{SEN}(f)(\phi) \wedge_{\Sigma'} \text{SEN}(f)(\psi) \in T_{\Sigma'} \\ & \quad \text{iff} \quad \text{SEN}(f)(\phi), \text{SEN}(f)(\psi) \in T_{\Sigma'} \\ & \quad \text{iff} \quad \text{SEN}(f)(\phi'), \text{SEN}(f)(\psi') \in T_{\Sigma'} \\ & \quad \text{iff} \quad \text{SEN}(f)(\phi') \wedge_{\Sigma'} \text{SEN}(f)(\psi') \in T_{\Sigma'} \\ & \quad \text{iff} \quad \text{SEN}(f)(\phi' \wedge_\Sigma \psi') \in T_{\Sigma'}. \end{aligned}$$

Thus, $\langle \phi \wedge_\Sigma \psi, \phi' \wedge_\Sigma \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}}(T)$ and $\tilde{\Lambda}^{\mathbf{A}}(T)$ is a congruence system on $\mathbf{A}^\wedge$.

The fact that $\tilde{\Lambda}^{\mathbf{A}}(D)$ and $\tilde{\Lambda}^{\mathbf{A}, D}(X)$ are congruence systems on $\mathbf{A}^\wedge$ now follow from the relationships outlined before Lemma 1452. $\blacksquare$

The Conjunction Property also satisfies a transfer property to the effect that a given π -institution has the Conjunction Property if and only if all its π -structure models have the Conjunction Property.

Proposition 1471 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\wedge^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^b$ if and only if, for every $\mathcal{I}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$.*

Proof: Suppose that $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^b$. Then, by Propositions 1468 and 1459, $\mathbb{L}$ has the Conjunction Property with respect to $\wedge$.

The converse is trivial, since $\langle \mathcal{F}, C \rangle \in \text{Str}(\mathcal{I})$, where $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$. ■

Finally, we show that if a π -institution $\mathcal{I}$ has the Conjunction Property, then any finitary $\mathcal{I}$ -structure with the Congruence Property is full.

Proposition 1472 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\wedge^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ a finitary $\mathcal{I}$ -structure, which has no theorems if $\mathcal{I}$ has no theorems. If $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^b$ and $\mathbb{L}$ has the strong Congruence Property, then $\mathbb{L}$ is a full $\mathcal{I}$ -structure.*

Proof: Suppose $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a finitary $\mathcal{I}$ -structure, without theorems, if $\mathcal{I}$ has no theorems, satisfying the strong Congruence Property. Our goal is to show that $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. We denote by $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ the bilogical quotient morphism.

Assume, first, that $T \in \mathcal{D}^*$. Then $\pi^{-1}(T) \in \mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{D})$, by Proposition 1422. Hence, by Corollary 55, $T \in \text{ThFam}^{\mathcal{I}}(\mathcal{A}^*)$. We conclude that $\mathcal{D}^* \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

Conversely, assume that $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. If $T = \emptyset$, then $\mathcal{I}$ does not have theorems. Thus, by hypothesis, $\emptyset \in \mathcal{D}$ and, therefore, $\emptyset \in \mathcal{D}^*$. Suppose, next, that $T \neq \emptyset$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \mathbf{SEN}(\Sigma)$, such that $\phi \in D_{\Sigma}^*(T_{\Sigma})$. By hypothesis and Proposition 1402, there exist $\phi_0, \dots, \phi_{n-1} \in T_{\Sigma}$, such that $\phi \in D_{\Sigma}^*(\phi_0, \dots, \phi_{n-1})$. By the Conjunction Property and Proposition 1471, $\phi \in D_{\Sigma}^*(\phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1}))$. Therefore,

$$D_{\Sigma}^*(\phi \wedge_{\Sigma} (\phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1}))) = D_{\Sigma}^*(\phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1})).$$

By hypothesis, Proposition 1463 and Corollary 1462, we get that

$$\phi \wedge_{\Sigma} (\phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1})) = \phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1}).$$

Since $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and $\mathcal{I}$ has the Conjunction Property with respect to $\wedge^b$, $\phi_0, \dots, \phi_{n-1} \in T_{\Sigma}$ imply that $\phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1}) \in T_{\Sigma}$. Thus, by the displayed equation above, $\phi \wedge_{\Sigma} (\phi_0 \wedge_{\Sigma} (\dots \wedge_{\Sigma} \phi_{n-1})) \in T_{\Sigma}$. By Proposition 1471, $\phi \in T_{\Sigma}$. So we have $D_{\Sigma}^*(T_{\Sigma}) = T_{\Sigma}$ and, hence, $T \in \mathcal{D}^*$. Thus, $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and $\mathbb{L}$ is a full $\mathcal{I}$ -structure. ■

19.9.3 The Deduction-Detachment Theorem

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\rightarrow: \text{SEN}^2 \rightarrow \text{SEN}$ a binary natural transformation in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure.

- $\mathbb{L}$ has the **Modus Ponens** or **Detachment with respect to $\rightarrow$** if, for all $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \text{SEN}(\Sigma)$,

$$\phi \rightarrow_{\Sigma} \psi \in D_{\Sigma}(\Phi) \quad \text{implies} \quad \psi \in D_{\Sigma}(\Phi, \phi).$$

- $\mathbb{L}$ has the **Deduction Theorem with respect to $\rightarrow$** if, for all $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \text{SEN}(\Sigma)$,

$$\psi \in D_{\Sigma}(\Phi, \phi) \quad \text{implies} \quad \phi \rightarrow_{\Sigma} \psi \in D_{\Sigma}(\Phi).$$

- $\mathbb{L}$ has the **Deduction Detachment Theorem with respect to $\rightarrow$** if it has both the Modus Ponens and the Deduction Theorem with respect to $\rightarrow$.

Structures that have the Deduction Detachment Theorem always have theorems. The following proposition gives a few of those theorems that are inspired by classical propositional calculus.

Proposition 1473 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\rightarrow: \text{SEN}^2 \rightarrow \text{SEN}$ a binary natural transformation in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure that has the Deduction Detachment Theorem with respect to $\rightarrow$. Then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi, \chi \in \text{SEN}(\Sigma)$,*

- (a) $\phi \rightarrow_{\Sigma} \phi \in \text{Thm}_{\Sigma}(\mathbb{L})$;
- (b) $\phi \rightarrow_{\Sigma} (\psi \rightarrow_{\Sigma} \phi) \in \text{Thm}_{\Sigma}(\mathbb{L})$;
- (c) $(\phi \rightarrow_{\Sigma} (\psi \rightarrow_{\Sigma} \chi)) \rightarrow_{\Sigma} ((\phi \rightarrow_{\Sigma} \psi) \rightarrow_{\Sigma} (\phi \rightarrow_{\Sigma} \chi)) \in \text{Thm}_{\Sigma}(\mathbb{L})$.

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\phi, \psi, \chi \in \text{SEN}(\Sigma)$.

- (a) Since $\phi \in D_{\Sigma}(\phi)$, we get by the Deduction Theorem, $\phi \rightarrow_{\Sigma} \phi \in D_{\Sigma}(\emptyset)$. So $\phi \rightarrow_{\Sigma} \phi \in \text{Thm}_{\Sigma}(\mathbb{L})$.
- (b) Since $\phi \in D_{\Sigma}(\phi, \psi)$, we get, by the Deduction Theorem, $\psi \rightarrow_{\Sigma} \phi \in D_{\Sigma}(\phi)$. By yet another application of the Deduction Theorem, we conclude that $\phi \rightarrow_{\Sigma} (\psi \rightarrow_{\Sigma} \phi) \in D_{\Sigma}(\emptyset)$. Therefore, $\phi \rightarrow_{\Sigma} (\psi \rightarrow_{\Sigma} \phi) \in \text{Thm}_{\Sigma}(\mathbb{L})$.
- (c) Since $\phi \rightarrow_{\Sigma} \psi \in D_{\Sigma}(\phi \rightarrow_{\Sigma} \psi)$ and $\phi \rightarrow_{\Sigma} (\psi \rightarrow_{\Sigma} \chi) \in D_{\Sigma}(\phi \rightarrow_{\Sigma} (\psi \rightarrow_{\Sigma} \chi))$, we get, by Modus Ponens, $\psi \in D_{\Sigma}(\phi \rightarrow_{\Sigma} \psi, \phi)$ and $\psi \rightarrow_{\Sigma} \chi \in$

$D_\Sigma(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi), \phi)$. Moreover, since $\psi \rightarrow_\Sigma \chi \in D_\Sigma(\psi \rightarrow_\Sigma \chi)$, we get, by Modus Ponens, $\chi \in D_\Sigma(\psi \rightarrow_\Sigma \chi, \psi)$. Thus, we obtain

$$\chi \in D_\Sigma(\psi \rightarrow_\Sigma \chi, \psi) \subseteq D_\Sigma(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi), \phi \rightarrow_\Sigma \psi, \phi).$$

By the Deduction Theorem, $\phi \rightarrow_\Sigma \chi \in D_\Sigma(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi), \phi \rightarrow_\Sigma \psi)$. By another application of the Deduction Theorem, $(\phi \rightarrow_\Sigma \psi) \rightarrow_\Sigma (\phi \rightarrow_\Sigma \chi) \in D_\Sigma(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi))$. A final application of the Deduction Theorem yields

$$(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi)) \rightarrow_\Sigma ((\phi \rightarrow_\Sigma \psi) \rightarrow_\Sigma (\phi \rightarrow_\Sigma \chi)) \in D_\Sigma(\emptyset).$$

Therefore, $(\phi \rightarrow_\Sigma (\psi \rightarrow_\Sigma \chi)) \rightarrow_\Sigma ((\phi \rightarrow_\Sigma \psi) \rightarrow_\Sigma (\phi \rightarrow_\Sigma \chi)) \in \text{Thm}_\Sigma(\mathbb{I}\mathbb{L})$. $\blacksquare$

Corollary 1474 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ a binary natural transformation in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, which has the Deduction Detachment Theorem with respect to $\rightarrow^b$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, and every $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$, $T \neq \emptyset$. Consequently, for every $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle \in \text{Str}(\mathcal{I})$, $\text{Thm}(\mathbb{I}\mathbb{L}) \neq \emptyset$.*

Proof: Clear by Proposition 1473. $\blacksquare$

We now give a characterization of the Modus Ponens property.

Proposition 1475 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\rightarrow: \text{SEN}^2 \rightarrow \text{SEN}$ in N , and $\mathbb{I}\mathbb{L} = \langle \mathcal{A}, D \rangle$ a π -structure. $\mathbb{I}\mathbb{L}$ has the Modus Ponens with respect to $\rightarrow$ if and only if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,*

$$\psi \in D_\Sigma(\phi, \phi \rightarrow_\Sigma \psi)$$

if and only if, for all $T \in \text{ThFam}(\mathbb{I}\mathbb{L})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,

$$\phi \in T_\Sigma \quad \text{and} \quad \phi \rightarrow_\Sigma \psi \in T_\Sigma \quad \text{imply} \quad \psi \in T_\Sigma.$$

Proof: Suppose, first, that $\mathbb{I}\mathbb{L}$ has the Modus Ponens with respect to $\rightarrow$ and let $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$. Then $\phi \rightarrow_\Sigma \psi \in D_\Sigma(\phi \rightarrow_\Sigma \psi)$, whence, by the Modus Ponens, $\psi \in D_\Sigma(\phi \rightarrow_\Sigma \psi, \phi)$. Conversely, suppose, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$, $\psi \in D_\Sigma(\phi, \phi \rightarrow_\Sigma \psi)$ and let $\Phi \subseteq \text{SEN}(\Sigma)$, such that $\phi \rightarrow_\Sigma \psi \in D_\Sigma(\Phi)$. Then, we have

$$\psi \in D_\Sigma(\phi, \phi \rightarrow_\Sigma \psi) \subseteq D_\Sigma(\Phi, \phi).$$

So $\mathbb{I}\mathbb{L}$ has the Modus Ponens with respect to $\rightarrow$.

The second equivalence is straightforward. $\blacksquare$

The Modus Ponens in a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ may also be characterized in terms of $\mathbf{F}$ -rules.

Proposition 1476 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ has the Modus Ponens with respect to $\rightarrow^b$ if and only if it satisfies the $\mathbf{F}$ -rule*

$$x, x \rightarrow^b y \vdash y.$$

Proof: $\mathcal{I}$ satisfies $x, x \rightarrow^b y \vdash y$ if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\psi \in C_\Sigma(\phi, \phi \rightarrow_\Sigma^b \psi)$$

if and only if, by Proposition 1475, $\mathcal{I}$ has the Modus Ponens with respect to $\rightarrow^b$. ■

Since the Modus Ponens in a π -institution is expressible in terms of $\mathbf{F}$ -rules, we may use Propositions 1459 and 1460 to draw the conclusions that the Modus Ponens transfers to all models and, moreover, that it is preserved by all bilogical morphisms.

Corollary 1477 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Modus Ponens with respect to $\rightarrow^b$, then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and every $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \text{Str}(\mathcal{I})$, $\mathbb{L}$ has the Modus Ponens with respect to $\rightarrow$.*

Proof: This follows by combining Proposition 1476 with Proposition 1459. ■

Corollary 1478 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ be N^b -algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be N^b -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle: \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism. $\mathbb{L}$ has the Modus Ponens with respect to $\rightarrow$ if and only if $\mathbb{L}'$ has the Modus Ponens with respect to $\rightarrow'$.*

Proof: The conclusion follows by combining Proposition 1476 with Proposition 1460. ■

It turns out that the Deduction Theorem also transfers under bilogical morphisms.

Proposition 1479 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ be N^b -algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be N^b -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle: \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism. $\mathbb{L}$ has the Deduction Theorem with respect to $\rightarrow$ if and only if $\mathbb{L}'$ has the Deduction Theorem with respect to $\rightarrow'$.*

Proof: Suppose, first, that $\mathbb{L}$ has the Deduction Theorem with respect to $\rightarrow$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \text{SEN}(\Sigma)$, such that

$$\alpha_\Sigma(\psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)).$$

Then, since $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, $\psi \in D_\Sigma(\Phi, \phi)$. Thus, since $\mathbb{L}$ has the Deduction Theorem, $\phi \rightarrow_\Sigma \psi \in D_\Sigma(\Phi)$. Again, by the fact that $\langle F, \alpha \rangle$ is a bilogical morphism, we obtain $\alpha_\Sigma(\phi \rightarrow_\Sigma \psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$ or, equivalently, $\alpha_\Sigma(\phi) \rightarrow'_{F(\Sigma)} \alpha_\Sigma(\psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Since $\langle F, \alpha \rangle$ is surjective, we conclude that $\mathbb{L}'$ also has the Deduction Theorem with respect to $\rightarrow'$.

Suppose, conversely, that $\mathbb{L}'$ has the Deduction Theorem with respect to $\rightarrow'$ and let $\Sigma \in |\mathbf{Sign}|$, $\Phi \cup \{\phi, \psi\} \subseteq \text{SEN}(\Sigma)$, such that $\psi \in D_\Sigma(\Phi, \phi)$. Since $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, we get that

$$\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)).$$

Since $\mathbb{L}'$ has the Deduction Theorem with respect to $\rightarrow'$, $\alpha_\Sigma(\phi) \rightarrow'_{F(\Sigma)} \alpha_\Sigma(\psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$ or, equivalently, $\alpha_\Sigma(\phi \rightarrow_\Sigma \psi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Again by the fact that $\langle F, \alpha \rangle$ is a bilogical morphism, we get $\phi \rightarrow_\Sigma \psi \in D_\Sigma(\Phi)$. Therefore, $\mathbb{L}$ also has the Deduction Theorem with respect to $\rightarrow$. ■

In an analog of Theorem 1470, we prove that, in case a π -structure has the Deduction Detachment Theorem, with respect to a binary natural transformation, then, Frege relation systems defined on the π -structure are congruence systems if one restricts to the category of natural transformations generated by the binary natural transformation.

Proposition 1480 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\rightarrow : \text{SEN}^2 \rightarrow \text{SEN}$ in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ be a π -structure based on $\mathbf{A}$. If $\mathbb{L}$ has the Deduction Detachment Property with respect to $\rightarrow$, then $\tilde{\Lambda}^{\mathbf{A}}(D)$ is a congruence system on $\mathbf{A}^\rightarrow$. Moreover, for all $X \in \text{SenFam}(\mathbf{A})$, $\tilde{\Lambda}^{\mathbf{A}, D}(X)$ is also a congruence system on $\mathbf{A}^\rightarrow$.*

Proof: It suffices to show that, for all $X \in \text{SenFam}(\mathbf{A})$, all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \phi', \psi, \psi' \in \text{SEN}(\Sigma)$,

$$\langle \phi, \phi' \rangle, \langle \psi, \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}, D}(X) \quad \text{implies} \quad \langle \phi \rightarrow_\Sigma \psi, \phi' \rightarrow_\Sigma \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}, D}(X).$$

So, suppose $X \in \text{SenFam}(\mathbf{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi, \phi', \psi, \psi' \in \text{SEN}(\Sigma)$, such that $\langle \phi, \phi' \rangle, \langle \psi, \psi' \rangle \in \tilde{\Lambda}_\Sigma^{\mathbf{A}, D}(X)$. Thus, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$,

$$\begin{aligned} D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi)) &= D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi')), \\ D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\psi)) &= D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\psi')). \end{aligned}$$

Now, using the Modus Ponens with respect to $\rightarrow$ and the displayed equations, we get

$$\begin{aligned} \text{SEN}(f)(\psi) \in D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi) \rightarrow_{\Sigma'} \text{SEN}(f)(\psi), \text{SEN}(f)(\phi)), \\ \text{SEN}(f)(\phi) \in D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi')). \end{aligned}$$

Therefore,

$$\begin{aligned} \text{SEN}(f)(\psi') &\in D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\psi)) \\ &\subseteq D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi) \rightarrow_{\Sigma'} \text{SEN}(f)(\psi), \text{SEN}(f)(\phi)) \\ &\subseteq D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi) \rightarrow_{\Sigma'} \text{SEN}(f)(\psi), \text{SEN}(f)(\phi')). \end{aligned}$$

By the Deduction Theorem, we now get

$$\text{SEN}(f)(\phi') \rightarrow_{\Sigma'} \text{SEN}(f)(\psi') \in D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi) \rightarrow_{\Sigma'} \text{SEN}(f)(\psi)).$$

This is equivalent to $\text{SEN}(f)(\phi' \rightarrow_{\Sigma} \psi') \in D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi \rightarrow_{\Sigma} \psi))$. Thus, by symmetry, we get that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $f \in \mathbf{Sign}(\Sigma, \Sigma')$, $D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi \rightarrow_{\Sigma} \psi)) = D_{\Sigma'}(X_{\Sigma'}, \text{SEN}(f)(\phi' \rightarrow_{\Sigma} \psi'))$ and, we conclude that $\langle \phi \rightarrow_{\Sigma} \psi, \phi' \rightarrow_{\Sigma} \psi' \rangle \in \widetilde{\Lambda}_{\Sigma}^{\mathbf{A}, D}(X)$. ■

Our next goal is to show that, if a finitary π -institution $\mathcal{I}$ has the Deduction Detachment Theorem, then every full $\mathcal{I}$ -structure also has the Deduction Detachment Theorem.

Theorem 1481 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\rightarrow^b$, then every full $\mathcal{I}$ -structure $\mathbb{I} = \langle \mathcal{A}, D \rangle$ has the Deduction Detachment Theorem with respect to $\rightarrow$.*

Proof: Suppose $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\rightarrow^b$. By Corollary 1430, Corollary 1478 and Proposition 1479, it is enough to show that every $\mathcal{I}$ -structure of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Deduction Detachment Theorem with respect to $\rightarrow$. By Corollary 1477, every $\mathcal{I}$ -structure has the Modus Ponens with respect to $\rightarrow$. So it suffices to show that $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Deduction Theorem with respect to $\rightarrow$, i.e., that, for all $\Sigma' \in |\mathbf{Sign}|$ and all $\Phi' \cup \{\phi', \psi'\} \subseteq \text{SEN}(\Sigma')$,

$$\psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi') \text{ implies } \phi' \rightarrow_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi').$$

We do this, using Proposition 114, by applying induction on $n < \omega$ to show that, for all $n < \omega$,

$$\psi' \in \Xi_{\Sigma'}^n(\Phi', \phi') \text{ implies } \phi' \rightarrow_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi').$$

For $n = 0$, we get $\psi' \in \Xi_{\Sigma'}^0(\Phi', \phi') = \Phi' \cup \{\phi'\}$.

- If $\psi' = \phi'$, then $\phi' \rightarrow_{\Sigma'} \psi' = \phi' \rightarrow_{\Sigma'} \phi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\emptyset) \subseteq C_{\Sigma'}^{\mathcal{A}, \mathcal{I}}(\Phi')$, because of Proposition 1473.
- If $\psi' \in \Phi'$, then $\psi' \rightarrow_{\Sigma'} (\phi' \rightarrow_{\Sigma'} \psi') \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\emptyset) \subseteq C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi')$, again by Proposition 1473. Since $\psi' \in \Phi' \subseteq C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi')$, we get by the Modus Ponens, $\phi' \rightarrow_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi')$.

Assume, next that, if, for some $i < n$, $\psi' \in \Xi_{\Sigma}^i(\Phi', \phi')$, then $\phi' \rightarrow_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi')$. Consider $\psi' \in \Xi_{\Sigma'}^n(\Phi', \phi')$. By definition, there exists $\Sigma \in |\mathbf{Sign}^b|$, such that $F(\Sigma) = \Sigma'$, and $\Phi \cup \{\phi, \psi\} \subseteq \text{SEN}^b(\Sigma)$, such that

$$\psi \in C_{\Sigma}(\Phi, \phi), \quad \alpha_{\Sigma}(\Phi) \subseteq \Xi_{\Sigma'}^{n-1}(\Phi', \phi'), \quad \alpha_{\Sigma}(\phi) = \phi', \quad \alpha_{\Sigma}(\psi) = \psi'.$$

Now, we have, on the one hand, by the Induction Hypothesis, $\phi' \rightarrow_{\Sigma'} \alpha_{\Sigma}(\chi) \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi')$, for all $\chi \in \Phi$. On the other hand, since $\psi \in C_{\Sigma}(\Phi, \phi)$, we get, using Modus Ponens,

$$\psi \in C_{\Sigma}(\Phi, \phi) \subseteq C_{\Sigma}(\{\phi \rightarrow_{\Sigma}^b \chi : \chi \in \Phi\}, \phi)$$

and, therefore, by the Deduction Theorem, $\phi \rightarrow_{\Sigma}^b \psi \in C_{\Sigma}(\{\phi \rightarrow_{\Sigma}^b \chi : \chi \in \Phi\})$. Therefore, we obtain

$$\phi' \rightarrow_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\{\phi' \rightarrow_{\Sigma'} \alpha_{\Sigma}(\chi) : \chi \in \Phi\}).$$

Finally, we obtain

$$\begin{aligned} \phi' \rightarrow_{\Sigma'} \psi' &\in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\{\phi' \rightarrow_{\Sigma'} \alpha_{\Sigma}(\chi) : \chi \in \Phi\}) \\ &\subseteq C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi')) \\ &= C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi'). \end{aligned}$$

We conclude that $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Deduction Detachment Theorem and therefore, every full $\mathcal{I}$ -structure does also. $\blacksquare$

Finally, we show that if a π -institution has the Deduction Detachment Theorem, then every finitary $\mathcal{I}$ -structure, with the Deduction Theorem and the Congruence Property is a full $\mathcal{I}$ -structure.

Proposition 1482 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution that has the Deduction Detachment Theorem with respect to $\rightarrow^b$. If $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a finitary $\mathcal{I}$ -structure with the Deduction Theorem and the strong Congruence Property, then $\mathbb{L}$ is a full $\mathcal{I}$ -structure.*

Proof: Suppose $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a finitary $\mathcal{I}$ -structure with the Deduction Theorem and the Congruence Property. Then, by Proposition 1422, $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and our goal is to show that $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

Suppose, first, that $T' \in \mathcal{D}^*$. Consider the bilgical quotient morphism $\langle I, \pi \rangle : \mathbb{L} \rightarrow \mathbb{L}^*$. Then we have $T = \pi^{-1}(T') \in \mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, by Corollary 55, $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. We conclude that $\mathcal{D}^* \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$.

Suppose, conversely, that $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Since $\mathcal{I}$ has the Deduction Detachment Theorem, by Corollary 1474, $T' \neq \emptyset$. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$, such that $\phi^* \in D_{\Sigma}^*(T'_{\Sigma})$. By the finitariness of $\mathbb{L}$ and Proposition 1402, there exist $\phi_0, \dots, \phi_{n-1} \in \text{SEN}(\Sigma)$, such that $\phi_0^*, \dots, \phi_{n-1}^* \in T'_{\Sigma}$ and

$\phi^* \in D_\Sigma^*(\phi_0^*, \dots, \phi_{n-1}^*)$. Since $\mathbb{L}$ has the Deduction Theorem, by Proposition 1479, so does $\mathbb{L}^*$, whence

$$\phi_0^* \rightarrow_\Sigma^* (\dots(\phi_{n-1}^* \rightarrow_\Sigma^* \phi^*) \dots) \in D_\Sigma^*(\emptyset) = D_\Sigma^*(\phi^* \rightarrow_\Sigma^* \phi^*),$$

the last equality, by Proposition 1473. Now we get

$$D_\Sigma^*(\phi_0^* \rightarrow_\Sigma^* (\dots(\phi_{n-1}^* \rightarrow_\Sigma^* \phi^*) \dots)) = D_\Sigma^*(\phi^* \rightarrow_\Sigma^* \phi^*).$$

Since $\mathbb{L}$ has the strong Congruence Property, by Proposition 1463, so does $\mathbb{L}^*$. Hence, by Corollary 1462,

$$\phi_0^* \rightarrow_\Sigma^* (\dots(\phi_{n-1}^* \rightarrow_\Sigma^* \phi^*) \dots) = \phi^* \rightarrow_\Sigma^* \phi^* \in T'_\Sigma.$$

Since $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$ and $\phi_0^*, \dots, \phi_{n-1}^* \in T'_\Sigma$, we get by the Modus Ponens, $\phi^* \in T'_\Sigma$. We conclude that $D_\Sigma^*(T'_\Sigma) \subseteq T'_\Sigma$ and, therefore, $T' \in \mathcal{D}^*$. So $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Hence, $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a full $\mathcal{I}$ -structure. ■

19.9.4 The Property of Disjunction

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\vee : \text{SEN}^2 \rightarrow \text{SEN}$ a binary natural transformation in N , and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ a π -structure.

$\mathbb{L}$ has the **Disjunction Property with respect to $\vee$** if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi, \psi\} \subseteq \text{SEN}(\Sigma)$,

$$D_\Sigma(\Phi, \phi \vee_\Sigma \psi) = D_\Sigma(\Phi, \phi) \cap D_\Sigma(\Phi, \psi).$$

In the next proposition, we discuss some of the $\mathbf{F}(\mathbf{g})$ rules that a π -institution having the Disjunction Property satisfies.

Proposition 1483 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\vee^b : (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Disjunction Property with respect to $\vee^b$, then $\mathcal{I}$ satisfies the following $\mathbf{F}$ -grules:*

- (a) $x \vdash x \vee^b y$ and $y \vdash x \vee^b y$;
- (b) $\frac{X, x \vdash z, \quad X, y \vdash z}{X, x \vee^b y \vdash z}$, where X consists of any set of projections;
- (c) $x \vee^b y \vdash y \vee^b x$;
- (d) $x \vdash x \vee^b x$ and $x \vee^b x \vdash x$.

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi, \psi, \chi\} \subseteq \text{SEN}^b(\Sigma)$.

- (a) By the Disjunction Property, $\phi \vee_\Sigma^b \psi \in C_\Sigma(\phi) \cap C_\Sigma(\psi)$.

- (b) Suppose $\chi \in C_\Sigma(\Phi, \phi)$ and $\chi \in C_\Sigma(\Phi, \psi)$. Then, by the Disjunction Property,

$$\chi \in C_\Sigma(\Phi, \phi) \cap C_\Sigma(\Phi, \psi) = C_\Sigma(\Phi, \phi \vee_\Sigma^b \psi).$$

- (c) We have, using the Disjunction Property,

$$\begin{aligned} \psi \vee_\Sigma^b \phi &\in C_\Sigma(\psi \vee_\Sigma^b \phi) = C_\Sigma(\psi) \cap C_\Sigma(\phi) \\ &= C_\Sigma(\phi) \cap C_\Sigma(\psi) = C_\Sigma(\phi \vee_\Sigma^b \psi). \end{aligned}$$

- (d) We have

$$\phi \vee_\Sigma^b \phi \in C_\Sigma(\phi \vee_\Sigma^b \phi) = C_\Sigma(\phi) \cap C_\Sigma(\phi) = C_\Sigma(\phi)$$

and, also,

$$\phi \in C_\Sigma(\phi) = C_\Sigma(\phi) \cap C_\Sigma(\phi) = C_\Sigma(\phi \vee_\Sigma^b \phi). \quad \blacksquare$$

It is not difficult to see that the Disjunction Property is also preserved under bilogical morphisms.

Proposition 1484 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\vee^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \mathbf{SEN}', N' \rangle$ be N^b -algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be N^b -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a bilogical morphism. $\mathbb{L}$ has the Disjunction Property with respect to $\vee$ if and only if $\mathbb{L}'$ has the Disjunction Property with respect to $\vee'$.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi, \psi\} \subseteq \mathbf{SEN}(\Sigma)$. Then, since $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ is a bilogical morphism, we have, using Proposition 1397,

$$\begin{aligned} D_\Sigma(\Phi, \phi \vee_\Sigma \psi) &= \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee'_{F(\Sigma)} \alpha_\Sigma(\psi))); \\ D_\Sigma(\Phi, \phi) \cap D_\Sigma(\Phi, \psi) &= \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \\ &\quad \cap \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi))) \\ &= \alpha_\Sigma^{-1}(D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \\ &\quad \cap D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi))). \end{aligned}$$

Now, using the surjectivity of $\langle F, \alpha \rangle$, we get that

$$D_\Sigma(\Phi, \phi \vee_\Sigma \psi) = D_\Sigma(\Phi, \phi) \cap D_\Sigma(\Phi, \psi)$$

if and only if

$$\begin{aligned} D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee'_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ = D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap D'_{F(\Sigma)}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)) \end{aligned}$$

Once more, taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\mathbb{L}$ has the Disjunction Property with respect to $\vee$ if and only if $\mathbb{L}'$ has the Disjunction Property with respect to $\vee'$. $\blacksquare$

Using induction, we can extend the defining equation of the Disjunction Property so that we can accommodate a finite number of conjunctions instead of only a single conjunction.

Proposition 1485 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\vee : \text{SEN}^2 \rightarrow \text{SEN}$ in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure. If $\mathbb{L}$ has the Disjunction Property with respect to $\vee$, then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi_0, \dots, \phi_{n-1}\} \subseteq \text{SEN}(\Sigma)$,*

$$D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi) = D_\Sigma(\Phi, \phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\Phi, \psi).$$

Proof: First, note that, for all $\Sigma \in |\mathbf{Sign}|$, all $\Phi \cup \{\phi_0, \dots, \phi_{n-1}, \psi\} \subseteq \text{SEN}(\Sigma)$ and all $i < n$,

$$\begin{aligned} \phi_i \vee_\Sigma \psi &\in D_\Sigma(\Phi, \phi_i) \cap D_\Sigma(\Phi, \psi) \\ &\subseteq D_\Sigma(\Phi, \phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\Phi, \psi). \end{aligned}$$

Thus, we get

$$D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi) \subseteq D_\Sigma(\Phi, \phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\Phi, \psi).$$

For the reverse inclusion, we use induction on n .

For $n = 1$, by the Disjunction Property, we get $D_\Sigma(\Phi, \phi_0) \cap D_\Sigma(\Phi, \psi) = D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi)$.

Assume that the inclusion holds for n .

Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi_0, \dots, \phi_n, \psi\} \subseteq \text{SEN}(\Sigma)$. Then we have

$$\begin{aligned} &D_\Sigma(\Phi, \phi_0, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi) \\ &= D_\Sigma(\Phi, \phi_0, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi) \cap D_\Sigma(\Phi, \psi) \\ &\subseteq D_\Sigma(\Phi, \phi_0, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \psi) \\ &\subseteq D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \phi_1, \dots, \phi_n) \cap D_\Sigma(\Phi, \phi_0 \vee_\Sigma \psi, \psi) \\ &\subseteq D_\Sigma(\Phi, \phi_0, \vee_\Sigma \psi, \phi_1 \vee_\Sigma \psi, \dots, \phi_n \vee_\Sigma \psi). \end{aligned}$$

Hence the inclusion - and, therefore, the equation - holds for all $n < \omega$. $\blacksquare$

Another property of structures having disjunction is that, if a specific entailment with a finite number of premises holds and the hypotheses are disjoined with the same sentence, then the disjunction of the conclusion with the same sentence follows from the disjoined hypotheses.

Lemma 1486 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\vee : \text{SEN}^2 \rightarrow \text{SEN}$ in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure. If $\mathbb{L}$ has the Disjunction Property with respect to $\vee$, then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi_0, \phi_{n-1}, \phi, \psi \in \text{SEN}(\Sigma)$,*

$$\phi \in D_\Sigma(\phi_0, \dots, \phi_{n-1}) \text{ implies } \phi \vee_\Sigma \psi \in D_\Sigma(\phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi).$$

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\phi_0, \phi_{n-1}, \phi, \psi \in \text{SEN}(\Sigma)$. By Proposition 1485,

$$D_\Sigma(\phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi) = D_\Sigma(\phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\psi).$$

But, by hypothesis, $\phi \in D_\Sigma(\phi_0, \dots, \phi_{n-1})$. So we get

$$\begin{aligned} \phi \vee_\Sigma \psi &\in D_\Sigma(\phi) \cap D_\Sigma(\psi) \\ &\subseteq D_\Sigma(\phi_0, \dots, \phi_{n-1}) \cap D_\Sigma(\psi) \\ &= D_\Sigma(\phi_0 \vee_\Sigma \psi, \dots, \phi_{n-1} \vee_\Sigma \psi). \end{aligned}$$

■

Our final goal is to show that, if a finitary π -institution has the Disjunction Property, then every full $\mathcal{I}$ -structure also has the Disjunction Property. To accomplish this, we prove, first, a lemma to the effect that, if an entailment holds in a model then the disjunct of the conclusion with an arbitrary sentence is entailed by the same premises except for one, which is replaced by the disjunct of the original with the same sentence.

Lemma 1487 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\vee^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$, which has the Disjunction Property with respect to $\vee^b$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\Sigma' \in |\mathbf{Sign}|$ and all $\Phi' \cup \{\phi', \psi', \chi'\} \subseteq \mathbf{SEN}(\Sigma')$,*

$$\chi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi') \quad \text{implies} \quad \chi' \vee_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi' \vee_{\Sigma'} \psi').$$

Proof: Let $\Sigma' \in |\mathbf{Sign}|$ and $\Phi' \cup \{\phi', \psi', \chi'\} \subseteq \mathbf{SEN}(\Sigma')$. By Proposition 114, $C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi') = \Xi_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi') = \bigcup_{n < \omega} \Xi_{\Sigma'}^n(\Phi', \phi')$. We show by induction on $n < \omega$ that, for all $n < \omega$

$$\chi' \in \Xi_{\Sigma'}^n(\Phi', \phi') \quad \text{implies} \quad \chi' \vee_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi' \vee_{\Sigma'} \psi').$$

If $n = 0$, the hypothesis is $\chi' \in \Xi_{\Sigma'}^0(\Phi', \phi') = \Phi' \cup \{\phi'\}$.

- If $\chi' = \phi'$, then the conclusion follows trivially.
- Suppose that $\chi' \in \Phi'$. Then, we have $\chi' \vee_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\chi') \subseteq C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi') \subseteq C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi' \vee_{\Sigma'} \psi')$, where the first inclusion follows by Propositions 1483 and 1459.

Assume that the displayed implication holds for all $i < n$. Let $\chi' \in \Xi_{\Sigma'}^n(\Phi', \phi')$. By definition, there exists $\Sigma \in |\mathbf{Sign}^b|$, such that $F(\Sigma) = \Sigma'$, and $\phi_0, \dots, \phi_{k-1}, \chi \in \mathbf{SEN}^b(\Sigma)$, such that

$$\chi \in C_\Sigma(\phi_0, \dots, \phi_{k-1}), \quad \alpha_\Sigma(\chi) = \chi', \quad \alpha_\Sigma(\phi_i) \in \Xi_{\Sigma'}^{n-1}(\Phi', \phi'), \quad i < k.$$

By the induction hypothesis, $\alpha_\Sigma(\phi_i) \vee_{\Sigma'} \psi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi' \vee_{\Sigma'} \psi')$, for all $i < k$. Note that, by the surjectivity of $\langle F, \alpha \rangle$, there exists $\psi \in \mathbf{SEN}(\Sigma)$, such that $\alpha_\Sigma(\psi) = \psi'$. Since $\chi \in C_\Sigma(\phi_0, \dots, \phi_{k-1})$, we get, by Lemma 1486, $\chi \vee_\Sigma^b \psi \in C_\Sigma(\phi_0 \vee_\Sigma^b \psi, \dots, \phi_{k-1} \vee_\Sigma^b \psi)$. Therefore, applying $\langle F, \alpha \rangle$,

$$\begin{aligned} \chi' \vee_{\Sigma'} \psi' &\in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\phi_0) \vee_{\Sigma'} \psi', \dots, \alpha_\Sigma(\phi_{k-1}) \vee_{\Sigma'} \psi') \\ &\subseteq C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\Phi', \phi' \vee_{\Sigma'} \psi'). \end{aligned}$$

Thus, the displayed formula holds for all $n < \omega$, yielding the conclusion. ■

Finally, we show that all full models of a given finitary π -institution with the Disjunction Property also have the Disjunction Property.

Theorem 1488 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\vee^b : (\mathbf{SEN}^b)^2 \rightarrow \mathbf{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Disjunction Property with respect to $\vee^b$, then every full $\mathcal{I}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ has the Disjunction Property with respect to $\vee$.*

Proof: By Corollary 1430 and Proposition 1484, it suffices to show that, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi, \psi\} \subseteq \mathbf{SEN}^b(\Sigma)$,

$$\begin{aligned} C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ = C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)). \end{aligned}$$

By Propositions Propositions 1483 and 1459, we have

$$\begin{aligned} C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ = C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)). \end{aligned}$$

Conversely, suppose that, for some $\chi \in \mathbf{SEN}^b(\Sigma)$,

$$\alpha_\Sigma(\chi) \in C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi)) \cap C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi)).$$

Then, by Lemma 1487,

$$\begin{aligned} \alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi) &\in C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)), \\ \alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi) &\in C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi)). \end{aligned}$$

Now we get

$$\begin{aligned} \alpha_\Sigma(\chi) &\in C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi)) \\ &\subseteq C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\psi) \vee_{F(\Sigma)} \alpha_\Sigma(\chi)) \\ &\subseteq C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\chi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)) \\ &\subseteq C_{F(\Sigma)}^{\mathcal{I}, \mathcal{A}}(\alpha_\Sigma(\Phi), \alpha_\Sigma(\phi) \vee_{F(\Sigma)} \alpha_\Sigma(\psi)). \end{aligned}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\mathbb{L}$ has the Disjunction Property with respect to $\vee$. ■

19.9.5 Reductio ad Absurdum

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\neg : \text{SEN} \rightarrow \text{SEN}$ a unary natural transformation in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$.

$\mathbb{L}$ has the **Intuitionistic Reductio ad Absurdum with respect to** $\neg$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$,

$$\neg_\Sigma \phi \in D_\Sigma(\Phi) \quad \text{if and only if} \quad D_\Sigma(\Phi, \phi) = \text{SEN}(\Sigma).$$

$\mathbb{L}$ has the **Reductio ad Absurdum with respect to** $\neg$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{if and only if} \quad D_\Sigma(\Phi, \neg_\Sigma \phi) = \text{SEN}(\Sigma).$$

The two properties of the Reductio ad Absurdum are related.

Proposition 1489 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\neg : \text{SEN} \rightarrow \text{SEN}$ in N , and $\mathbb{L} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$. $\mathbb{L}$ has the Reductio ad Absurdum with respect to $\neg$ if and only if it has the Intuitionistic Reductio ad Absurdum with respect to $\neg$ and, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi)$.*

Proof: Suppose, first, that $\mathbb{L}$ has the Reductio ad Absurdum with respect to $\neg$ and let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$.

Since $\neg_\Sigma \phi \in D_\Sigma(\neg_\Sigma \phi)$, we get $D_\Sigma(\neg_\Sigma \phi, \neg_\Sigma \neg_\Sigma \phi) = \text{SEN}(\Sigma)$. Therefore, $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi)$.

Suppose, next, that $\neg_\Sigma \phi \in D_\Sigma(\Phi)$. Note that, since $\phi \in D_\Sigma(\phi)$, we also have $D_\Sigma(\phi, \neg_\Sigma \phi) = \text{SEN}(\Sigma)$. So, finally, $\text{SEN}(\Sigma) = D_\Sigma(\phi, \neg_\Sigma \phi) \subseteq D_\Sigma(\Phi, \phi)$ and equality follows.

On the other hand, if $D_\Sigma(\Phi, \phi) = \text{SEN}(\Sigma)$, then $D_\Sigma(\Phi, \neg_\Sigma \neg_\Sigma \phi) = \text{SEN}(\Sigma)$, whence $\neg_\Sigma \phi \in D_\Sigma(\Phi)$.

Suppose, conversely, that $\mathbb{L}$ has the Intuitionistic Reductio ad Absurdum and that, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi)$, and let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$.

Suppose, first, $\phi \in D_\Sigma(\Phi)$. Since $\neg_\Sigma \phi \in D_\Sigma(\neg_\Sigma \phi)$, we get $D_\Sigma(\phi, \neg_\Sigma \phi) = \text{SEN}(\Sigma)$. Therefore, $\text{SEN}(\Sigma) = D_\Sigma(\phi, \neg_\Sigma \phi) \subseteq D_\Sigma(\Phi, \neg_\Sigma \phi)$.

On the other hand, if $D_\Sigma(\Phi, \neg_\Sigma \phi) = \text{SEN}(\Sigma)$, then $\neg_\Sigma \neg_\Sigma \phi \in D_\Sigma(\Phi)$, whence $\phi \in D_\Sigma(\neg_\Sigma \neg_\Sigma \phi) \subseteq D_\Sigma(\phi)$. ■

We also show for future reference that the Intuitionistic Reductio ad Absurdum is preserved under biological morphisms.

Proposition 1490 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\neg^b : \text{SEN}^b \rightarrow \text{SEN}^b$ in N^b , $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \mathbf{Sign}', \text{SEN}', N' \rangle$ be N^b -algebraic systems, $\mathbb{L} = \langle \mathbf{A}, D \rangle$, $\mathbb{L}' = \langle \mathbf{A}', D' \rangle$ be N^b -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism. $\mathbb{L}$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg$ if and only if $\mathbb{L}'$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg'$.*

Proof: Suppose $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$. Then, we have

$$\begin{aligned} \neg_{\Sigma}\phi \in D_{\Sigma}(\Phi) & \text{ iff } \alpha_{\Sigma}(\neg_{\Sigma}\phi) \in D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)) \\ & \text{ iff } \neg'_{F(\Sigma)}(\alpha_{\Sigma}(\phi)) \in D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)). \end{aligned}$$

Moreover, using the surjectivity of $\langle F, \alpha \rangle$,

$$D_{\Sigma}(\Phi, \phi) = \text{SEN}(\Sigma) \text{ iff } D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi), \alpha_{\Sigma}(\phi)) = \text{SEN}'(F(\Sigma)).$$

Thus, the equivalence

$$\neg_{\Sigma}\phi \in D_{\Sigma}(\Phi) \text{ iff } D_{\Sigma}(\Phi, \phi) = \text{SEN}(\Sigma)$$

holds if and only if the equivalence

$$\neg'_{F(\Sigma)}\alpha_{\Sigma}(\phi) \in D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)) \text{ iff } D'_{F(\Sigma)}(\alpha_{\Sigma}(\Phi), \alpha_{\Sigma}(\phi)) = \text{SEN}'(F(\Sigma))$$

holds. In other words, $\mathbb{IL}$ has the Intuitionistic Reduction ad Absurdum with respect to $\neg$ if and only if $\mathbb{IL}'$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg'$. ■

The Intuitionistic Reductio ad Absurdum is also closely related with are called inconsistent elements or inconsistencies.

Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\perp : \text{SEN} \rightarrow \text{SEN}$ a unary natural transformation in N , and $\mathbb{IL} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$. $\perp$ is an **inconsistency** in $\mathbb{IL}$ if, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$D_{\Sigma}(\perp_{\Sigma}\phi) = \text{SEN}(\Sigma).$$

Having an inconsistency is clearly expressible by an **F**-rule and, therefore, if a π -institution has an inconsistency then all its models do also.

Lemma 1491 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\perp^b : \text{SEN}^b \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\perp^b$ is an inconsistency in $\mathcal{I}$ if and only if $\mathcal{I}$ satisfies the **F**-rule $\perp^b x \vdash y$.*

Proof: We have that $\mathcal{I}$ satisfies $\perp^b x \vdash y$ if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, $\psi \in C_{\Sigma}(\perp^b_{\Sigma}\phi)$, if and only if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi \in \text{SEN}^b(\Sigma)$, $C_{\Sigma}(\perp^b_{\Sigma}\phi) = \text{SEN}(\Sigma)$, if and only if $\perp^b : \text{SEN}^b \rightarrow \text{SEN}^b$ is an inconsistency in $\mathcal{I}$. ■

Corollary 1492 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\perp^b : \text{SEN}^b \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\perp^b$ is an inconsistency in $\mathbb{IL}$, then, $\perp$ is an inconsistency in every $\mathcal{I}$ -structure $\mathbb{IL} = \langle \mathcal{A}, D \rangle$, for every **F**-algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$.*

Proof: By Lemma 1491 and Proposition 1459. ■

The following proposition exhibits the relation between the Intuitionistic Reductio ad Absurdum and inconsistencies.

Proposition 1493 *Let $\mathbf{A} = \langle \mathbf{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\rightarrow: \text{SEN}^2 \rightarrow \text{SEN}$, and $\mathbf{IL} = \langle \mathbf{A}, D \rangle$ a π -structure that has the Deduction Detachment Theorem with respect to $\rightarrow$. $\mathbf{IL}$ has the Intuitionistic Reductio ad Absurdum with respect to some $\neg: \text{SEN} \rightarrow \text{SEN}$ in N if and only if it has an inconsistency $\perp: \text{SEN} \rightarrow \text{SEN}$ in N . Moreover, in that case, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,*

$$D_\Sigma(\neg_\Sigma \phi) = D_\Sigma(\phi \rightarrow_\Sigma \perp_\Sigma \phi).$$

Proof: Suppose that $\mathbf{IL}$ has the Deduction Detachment Theorem with respect to $\rightarrow$.

Assume, first, that $\mathbf{IL}$ also has the Intuitionistic Reductio ad Absurdum with respect to $\neg$. Let $\perp: \text{SEN} \rightarrow \text{SEN}$ be defined, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, by

$$\perp_\Sigma \phi = \neg_\Sigma(\phi \rightarrow_\Sigma \phi).$$

First, note, that, since $\perp = \neg \circ \rightarrow \circ \langle p^{1,0}, p^{1,0} \rangle$ and both $\rightarrow$ and $\neg$ are in N , we get that $\perp$ is also in N . Moreover, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$,

$$\begin{aligned} & \neg_\Sigma(\phi \rightarrow_\Sigma \phi) \in D_\Sigma(\neg_\Sigma(\phi \rightarrow_\Sigma \phi)) \\ \text{iff } & D_\Sigma(\phi \rightarrow_\Sigma \phi, \neg_\Sigma(\phi \rightarrow_\Sigma \phi)) = \text{SEN}(\Sigma) \\ & \text{(by the Intuitionistic Reductio ad Absurdum)} \\ \text{iff } & D_\Sigma(\neg_\Sigma(\phi \rightarrow_\Sigma \phi)) = \text{SEN}(\Sigma). \\ & \text{(by Proposition 1473)} \end{aligned}$$

Thus, $\perp$ is an inconsistency in $\mathbf{IL}$.

Assume, conversely, that $\perp: \text{SEN} \rightarrow \text{SEN}$ is an inconsistency in $\mathbf{IL}$. Define $\neg: \text{SEN} \rightarrow \text{SEN}$, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi \in \text{SEN}(\Sigma)$, by

$$\neg_\Sigma \phi = \phi \rightarrow_\Sigma \perp_\Sigma \phi.$$

Since $\neg = \rightarrow \circ \langle p^{1,0}, \perp \rangle$ and, both $\rightarrow$ and $\perp$ are in N , it follows that $\neg$ is also in N . Moreover, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$, we have

$$\begin{aligned} \neg_\Sigma \phi \in D_\Sigma(\Phi) & \text{ iff } \phi \rightarrow_\Sigma \perp_\Sigma \phi \in D_\Sigma(\Phi) \\ & \text{ iff } \perp_\Sigma \phi \in D_\Sigma(\Phi, \phi) \\ & \text{ iff } D_\Sigma(\Phi, \phi) = \text{SEN}(\Sigma). \end{aligned}$$

Thus, $\mathbf{IL}$ has the Intuitionistic Reductio ad Absurdum with respect to $\neg$.

Finally, it remains to prove the last equality. Let $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$. On the one hand, we have, by the Modus Ponens, $\perp_\Sigma \phi \in D_\Sigma(\phi, \phi \rightarrow_\Sigma$

$\perp_\Sigma\phi$), whence, since $\perp$ is an inconsistency, $D_\Sigma(\phi, \phi \rightarrow_\Sigma \perp_\Sigma\phi) = \text{SEN}(\Sigma)$ and, hence, by the Intuitionistic Reductio ad Absurdum, $\neg_\Sigma\phi \in D_\Sigma(\phi \rightarrow_\Sigma \perp_\Sigma\phi)$. On the other hand, since $\neg_\Sigma\phi \in D_\Sigma(\neg_\Sigma\phi)$, by the Intuitionistic Reductio ad Absurdum, $D_\Sigma(\phi, \neg_\Sigma\phi) = \text{SEN}(\Sigma)$ and, hence, $\neg_\Sigma\phi \in D_\Sigma(\phi, \neg_\Sigma\phi)$. Therefore, by the Deduction Theorem, $\phi \rightarrow_\Sigma \perp_\Sigma\phi \in D_\Sigma(\neg_\Sigma\phi)$. These two parts allow us to conclude that $D_\Sigma(\neg_\Sigma\phi) = D_\Sigma(\phi \rightarrow_\Sigma \perp_\Sigma\phi)$. ■

Since both the Deduction Detachment Theorem and inconsistencies are inherited by the full models of a finitary π -institution, we obtain the following concerning transference of the Intuitionistic Reductio ad Absurdum by full models.

Corollary 1494 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\rightarrow^b: (\text{SEN}^b)^2 \rightarrow \text{SEN}^b$ and $\neg^b: \text{SEN}^b \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has the Deduction Detachment Theorem with respect to $\rightarrow^b$ and the Intuitionistic Reductio ad Absurdum with respect to $\neg^b$, then, for every $\mathbf{F}$ -algebraic system $\mathbf{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, every full $\mathcal{I}$ -structure $\mathbb{I} = \langle \mathbf{A}, D \rangle$ also has the Deduction Detachment Theorem with respect to $\rightarrow$ and the Intuitionistic Reductio ad Absurdum with respect to $\neg$.*

Proof: Assume the hypothesis and let $\mathbb{I} = \langle \mathbf{A}, D \rangle \in \text{FStr}(\mathcal{I})$. By Theorem 1481, $\mathbb{I}$ has the Deduction Detachment Theorem with respect to $\rightarrow$. By Proposition 1493, $\perp^b = \neg^b \circ \rightarrow^b \circ \langle p^{1,0}, p^{1,0} \rangle$ is an inconsistency in $\mathcal{I}$. Therefore, by Corollary 1492, $\perp$ is an inconsistency in $\mathbb{I}$. Finally, we use again Proposition 1493 to conclude that $\mathbb{I}$ has both the Deduction Detachment Theorem with respect to $\rightarrow$ and the Intuitionistic Reductio ad Absurdum with respect to $\neg$. ■

19.9.6 Modality Introduction

Let $\mathbf{A} = \langle \text{Sign}, \text{SEN}, N \rangle$ be an algebraic system, with $\# : \text{SEN} \rightarrow \text{SEN}$ a unary natural transformation in N , and $\mathbb{I} = \langle \mathbf{A}, D \rangle$ a π -structure based on $\mathbf{A}$. $\mathbb{I}$ has **Modality Introduction with respect to $\#$** if, for all $\Sigma \in |\text{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \quad \text{implies} \quad \#_\Sigma\phi \in D_\Sigma(\#_\Sigma\Phi),$$

where $\#_\Sigma\Phi = \{\#_\Sigma\chi : \chi \in \Phi\}$.

It turns out that Modality Introduction is also preserved under biological morphisms.

Proposition 1495 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\#^b: \text{SEN}^b \rightarrow \text{SEN}^b$ in N^b , $\mathbf{A} = \langle \text{Sign}, \text{SEN}, N \rangle$, $\mathbf{A}' = \langle \text{Sign}', \text{SEN}', N' \rangle$ be N^b -algebraic systems, $\mathbb{I} = \langle \mathbf{A}, D \rangle$, $\mathbb{I}' = \langle \mathbf{A}', D' \rangle$ be N^b -structures based on $\mathbf{A}$, $\mathbf{A}'$, respectively, and $\langle F, \alpha \rangle: \mathbb{I} \vdash \mathbb{I}'$ a biological morphism. $\mathbb{I}$ has the Modality Introduction with respect to $\#$ if and only if $\mathbb{I}'$ has the Modality Introduction with respect to $\#'$.*

Proof: Let $\Sigma \in |\mathbf{Sign}|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$. Then, since $\langle F, \alpha \rangle$ is a biological morphism, we have

$$\begin{aligned} \phi \in D_\Sigma(\Phi) & \text{ iff } \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)); \\ \#_\Sigma \phi \in D_\Sigma(\#_\Sigma \Phi) & \text{ iff } \#'_{F(\Sigma)} \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\#'_{F(\Sigma)} \alpha_\Sigma(\Phi)). \end{aligned}$$

Therefore, for all $\Sigma \in |\mathbf{Sign}|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}(\Sigma)$,

$$\phi \in D_\Sigma(\Phi) \text{ implies } \#_\Sigma \phi \in D_\Sigma(\#_\Sigma \Phi)$$

is equivalent to

$$\alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\alpha_\Sigma(\Phi)) \text{ implies } \#'_{F(\Sigma)} \alpha_\Sigma(\phi) \in D'_{F(\Sigma)}(\#'_{F(\Sigma)} \alpha_\Sigma(\Phi)).$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we conclude that $\mathbb{L}$ has Modality Introduction with respect to $\#$ if and only if $\mathbb{L}'$ has Modality Introduction with respect to $\#'$. $\blacksquare$

We conclude this section by showing that modality introduction is inherited by all full $\mathcal{I}$ -structures if $\mathcal{I}$ is a finitary π -institution possessing the property.

Proposition 1496 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, with $\#^b : \text{SEN}^b \rightarrow \text{SEN}^b$ in N^b , and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has Modality Introduction with respect to $\#^b$, then every full $\mathcal{I}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ has the Modality Introduction with respect to $\#$.*

Proof: By Corollary 1430 and Proposition 1495, it suffices to show that every $\mathcal{I}$ -structure of the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ has the Modality Introduction with respect to $\#$. Let $\Sigma' \in |\mathbf{Sign}|$ and $\Phi' \cup \{\phi'\} \subseteq \text{SEN}(\Sigma')$. By Proposition 114, it suffices to show that

$$\phi' \in \Xi_{\Sigma'}(\Phi') \text{ implies } \#_{\Sigma'} \phi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\#_{\Sigma'} \Phi').$$

We do this by applying induction on $n < \omega$ to show that, for all $n < \omega$,

$$\phi' \in \Xi_{\Sigma'}^n(\Phi') \text{ implies } \#_{\Sigma'} \phi' \in C_{\Sigma'}^{\mathcal{I}, \mathcal{A}}(\#_{\Sigma'} \Phi').$$

If $n = 0$, then the hypothesis is $\phi' \in \Xi_{\Sigma'}^0(\Phi') = \Phi'$ and the conclusion is trivial. Assume that the displayed formula holds, for all $i < n$ and assume $\Sigma' \in |\mathbf{Sign}|$ and $\Phi' \cup \{\phi'\} \subseteq \text{SEN}(\Sigma')$, such that $\phi' \in \Xi_{\Sigma'}^n(\Phi')$. Then, by definition, there exists $\Sigma \in |\mathbf{Sign}^b|$, such that $F(\Sigma) = \Sigma'$, and $\phi_0, \dots, \phi_{k-1}, \phi \in \text{SEN}^b(\Sigma)$, such that

$$\phi \in C_\Sigma(\phi_0, \dots, \phi_{k-1}), \quad \alpha_\Sigma(\phi) = \phi', \quad \alpha_\Sigma(\phi_i) \in \Xi_{\Sigma'}^{n-1}(\Phi'), \quad i < k.$$

By the induction hypothesis, for all $i < k$, $\#_{\Sigma'}\alpha_{\Sigma}(\phi_i) \in C_{\Sigma'}^{\mathcal{I},\mathcal{A}}(\#_{\Sigma'}\Phi')$. Moreover, since $\mathcal{I}$ has Modality Introduction with respect to $\#^b$, we get $\#_{\Sigma}^b\phi \in C_{\Sigma}(\#_{\Sigma}^b\phi_0, \dots, \#_{\Sigma}^b\phi_{k-1})$. Therefore, applying $\langle F, \alpha \rangle$,

$$\begin{aligned} \#_{F(\Sigma)}\phi' &\in C_{\Sigma'}^{\mathcal{I},\mathcal{A}}(\#_{F(\Sigma)}\alpha_{\Sigma}(\phi_0), \dots, \#_{F(\Sigma)}\alpha_{\Sigma}(\phi_{k-1})) \\ &\subseteq C_{\Sigma'}^{\mathcal{I},\mathcal{A}}(\#_{\Sigma}\Phi'). \end{aligned}$$

This proves the induction step and shows that $\mathbb{L}$ has the Modality Introduction with respect to $\#$. $\blacksquare$

19.10 $\mathcal{I}$ -Structures and Protoalgebraicity

We now work with an arbitrary π -institution $\mathcal{I}$ and look at its $\mathcal{I}$ -structures and their properties. We start with a characterization of protoalgebraicity involving $\mathcal{I}$ -structures.

Proposition 1497 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then the following conditions are equivalent.*

- (i) $\mathcal{I}$ is protoalgebraic;
- (ii) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and every $\mathcal{I}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\tilde{\Omega}^{\mathcal{A}}(D) = \Omega^{\mathcal{A}}(\text{Thm}(\mathbb{L}))$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and every $\mathcal{I}$ -matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, $\tilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathfrak{A})) = \Omega^{\mathcal{A}}(T)$;
- (iv) For every $T \in \text{ThFam}(\mathcal{I})$, $\tilde{\Omega}(\mathcal{I}^T) = \Omega(T)$.

Proof:

- (i) $\Rightarrow$ (ii) Assume $\mathcal{I}$ is protoalgebraic and let $\mathbb{L} = \langle \mathcal{A}, D \rangle$ be an $\mathcal{I}$ -structure. Then, by Proposition 1422, $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, by Theorem 179, $\Omega^{\mathcal{A}}$ is monotone on $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Hence, we get

$$\tilde{\Omega}^{\mathcal{A}}(D) = \bigcap \{ \Omega^{\mathcal{A}}(T) : T \in \mathcal{D} \} = \Omega^{\mathcal{A}}(\bigcap \mathcal{D}) = \Omega^{\mathcal{A}}(\text{Thm}(\mathbb{L})).$$

- (ii) $\Rightarrow$ (iii) Follows by applying (ii) to $\mathbb{L} = \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$.
- (iii) $\Rightarrow$ (iv) Follows by applying (iii) to $\mathcal{A} = \langle \mathcal{F}, T \rangle$, where, as usual, $\mathcal{F} = \langle \mathbf{F}, \langle I, \iota \rangle \rangle$, $\langle I, \iota \rangle : \mathbf{F} \rightarrow \mathbf{F}$ the identity morphism.
- (iv) $\Rightarrow$ (i) Suppose that, for every $T \in \text{ThFam}(\mathcal{I})$, $\tilde{\Omega}(\mathcal{I}^T) = \Omega(T)$ and let $T, T' \in \text{ThFam}(\mathcal{I})$, such that $T \leq T'$. Then $T' \in \text{ThFam}(\mathcal{I}^T)$, whence $\tilde{\Omega}(\mathcal{I}^T) \leq \Omega(T')$. But, by hypothesis, $\tilde{\Omega}(\mathcal{I}^T) = \Omega(T)$. Thus, we get $\Omega(T) \leq \Omega(T')$. We conclude that Ω is monotone on theory families and, therefore, $\mathcal{I}$ is protoalgebraic.

■

Recall that to a π -institution $\mathcal{I}$, we have associated two different classes of algebraic systems. On the one hand, the class $\text{AlgSys}^*(\mathcal{I})$ consists of the $\mathbf{F}$ -algebraic system reducts of the reduced $\mathcal{I}$ -matrix families. On the other, the class $\text{AlgSys}(\mathcal{I})$ consists of the $\mathbf{F}$ -algebraic system reducts of the reduced full $\mathcal{I}$ -structures, or, equivalently, as was shown in Proposition 1436, by the $\mathbf{F}$ -algebraic system reducts of the reduced $\mathcal{I}$ -structures. Under the hypothesis of protoalgebraicity, it turns out that the two classes $\text{AlgSys}(\mathcal{I})$ and $\text{AlgSys}^*(\mathcal{I})$ coincide.

Proposition 1498 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is protoalgebraic, then $\text{AlgSys}(\mathcal{I}) = \text{AlgSys}^*(\mathcal{I})$.*

Proof: By Theorem 1441, we know that $\text{AlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}(\mathcal{I})$. Assume, conversely, that $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \text{AlgSys}(\mathcal{I})$. Then, there exists, by Proposition 1436, $\mathcal{D} \in \text{ClFam}(\mathcal{A})$, such that $\tilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Delta^{\mathcal{A}}$. Thus, by Proposition 1497, $\tilde{\Omega}^{\mathcal{A}}(\cap \mathcal{D}) = \tilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Delta^{\mathcal{A}}$, whence, since $\cap \mathcal{D} \in \mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\mathcal{A} \in \text{AlgSys}^*(\mathcal{I})$. ■

Protoalgebraicity is strong enough to allow full $\mathcal{I}$ -structures on an algebraic system to be determined by their theorem systems.

Lemma 1499 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. If $\mathcal{I}$ is protoalgebraic and $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}, D' \rangle$ are full $\mathcal{I}$ structures based on $\mathcal{A}$, such that $\text{Thm}(\mathbb{L}) = \text{Thm}(\mathbb{L}')$, then $\mathbb{L} = \mathbb{L}'$.*

Proof: Since $\mathcal{I}$ is protoalgebraic, we have, by Proposition 1497,

$$\tilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Omega^{\mathcal{A}}(\text{Thm}(\mathbb{L})) = \Omega^{\mathcal{A}}(\text{Thm}(\mathbb{L}')) = \tilde{\Omega}^{\mathcal{A}}(\mathcal{D}').$$

By the Isomorphism Theorem 1445, $\tilde{\Omega}^{\mathcal{A}} : \text{FStr}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism, in particular one-to-one. So we get that $\mathbb{L} = \mathbb{L}'$. ■

For protoalgebraic π -institutions, it follows that all full $\mathcal{I}$ -models have the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle = \langle \mathcal{A}, \text{FiFam}^{\mathcal{A}}(\langle \mathcal{A}, T \rangle) \rangle$, i.e., their closure systems are principal filters in the lattice of $\mathcal{I}$ -filter families of the underlying algebraic system.

Theorem 1500 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is protoalgebraic if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\mathcal{I}$ -structures in $\text{FStr}^{\mathcal{I}}(\mathcal{A})$ have the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathfrak{A}) \rangle$, for some $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \text{MatFam}^{\mathcal{I}}(\mathcal{A})$.*

Proof: Assume, first, that $\mathcal{I}$ is protoalgebraic and let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \text{FStr}(\mathcal{I})$. Let $T = \text{Thm}(\mathbb{L})$ and set $\mathfrak{A} = \langle \mathcal{A}, T \rangle$. Clearly, $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathfrak{A})$. By protoalgebraicity and Proposition 1497, $\tilde{\Omega}^{\mathcal{A}}(\mathbb{L}) = \Omega^{\mathcal{A}}(T)$. Therefore, if $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T)$ denotes the quotient morphism, $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a biological morphism. Since $\mathbb{L} \in \text{FStr}(\mathcal{I})$, $\mathcal{D}^* = \text{ThFam}^{\mathcal{I}}(\mathcal{A}^*)$. But then, if $T' \in \text{ThFam}^{\mathcal{I}}(\mathfrak{A})$, $T \leq T'$, whence $\Omega^{\mathcal{A}}(T)$ is compatible with T' and, hence, by Corollary 56, $T'/\Omega^{\mathcal{A}}(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*) = \mathcal{D}^*$. Therefore, $T' = \pi^{-1}(T'/\Omega^{\mathcal{A}}(T)) \in \mathcal{D}$. So $\text{FiFam}^{\mathcal{I}}(\mathcal{A}) = \mathcal{D}$.

Suppose, conversely, that, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, all $\mathcal{I}$ -structures in $\text{FStr}^{\mathcal{I}}(\mathcal{A})$ have the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathfrak{A}) \rangle$, for some $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \text{MatFam}^{\mathcal{I}}(\mathcal{A})$. Let $T, T' \in \text{ThFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$. Since, by Theorem 1441, $\text{AlgSys}^*(\mathcal{I}) \subseteq \text{AlgSys}(\mathcal{I})$, $\Omega^{\mathcal{A}}(T) \in \text{ConSys}^{\mathcal{I}}(\mathcal{A})$. Therefore, by the Isomorphism Theorem 1445, there exists $\mathbb{L} = \langle \mathcal{A}, \mathcal{D} \rangle \in \text{FStr}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{\Omega}^{\mathcal{A}}(\mathcal{D}) = \Omega^{\mathcal{A}}(T)$. Let $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T)$ be the quotient morphism. Then $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a biological morphism and, since $\mathbb{L}$ is full, $\mathcal{D}^* = \text{FiFam}^{\mathcal{I}}(\mathcal{A}^*)$. Thus, $T = \pi^{-1}(T/\Omega^{\mathcal{A}}(T)) \in \mathcal{D}$. By hypothesis, $T \in \text{FiFam}^{\mathcal{I}}(\mathfrak{A})$, for some $\mathfrak{A} = \langle \mathcal{A}, T'' \rangle \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Thus, $T'' \leq T'$, whence $T' \in \text{FiFam}^{\mathcal{I}}(\mathfrak{A}) = \mathcal{D}$. We now get $\Omega^{\mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{A}}(\mathcal{D}) \leq \Omega^{\mathcal{A}}(T')$. So $\Omega^{\mathcal{A}}$ is monotone on $\mathcal{A}$. Since $\mathcal{A}$ was arbitrary, we conclude that $\mathcal{I}$ is protoalgebraic. ■

We proved that, for a protoalgebraic π -institution $\mathcal{I}$, all full $\mathcal{I}$ -structures have the form $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$, for some $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. We seek now to characterize those $\mathcal{I}$ -filter families T for which the pair $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is a full $\mathcal{I}$ -model, i.e., those $\mathcal{I}$ -filter families T that give rise, through the principal filters they determine in $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ to full $\mathcal{I}$ -structures.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. We define

$$\text{FiFam}^{\mathcal{I},f}(\mathcal{A}) = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \text{FStr}^{\mathcal{I}}(\mathcal{A})\}.$$

Using the Isomorphism Theorem 1445, it is not difficult to see that, under protoalgebraicity, there exists an order isomorphism between the poset determined by $\text{FiFam}^{\mathcal{I},f}(\mathcal{A})$ and the lattice of all $\mathcal{I}$ -congruence systems on $\mathcal{A}$.

Proposition 1501 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is protoalgebraic, then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$$

is an order isomorphism.

Proof: Consider the mapping $T \mapsto \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$. This is a mapping from $\text{FiFam}^{\mathcal{I},f}(\mathcal{A})$ into $\text{FStr}^{\mathcal{I}}(\mathcal{A})$, by the definition of $\text{FiFam}^{\mathcal{I},f}(\mathcal{A})$. Clearly, it is

one-to-one and both order preserving and order reflecting. If $\mathcal{I}$ is protoalgebraic, by Theorem 1500, it is also surjective. Hence, it is an order isomorphism. By the Isomorphism Theorem 1445, $\tilde{\Omega}^{\mathcal{A}} : \mathbf{FStr}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$ is also an order isomorphism. Thus, $T \mapsto \tilde{\Omega}^{\mathcal{A}}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$ is an order isomorphism from $\mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A})$ onto $\mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$. By Protoalgebraicity and Proposition 1497, we have $\tilde{\Omega}^{\mathcal{A}}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T) = \Omega^{\mathcal{A}}(T)$ and, moreover, by Proposition 1498, $\mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}) = \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$. Hence, we conclude that $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order-isomorphism. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. Define

$$\sim^{\mathcal{I}, \mathcal{A}} \subseteq \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^2$$

by setting, for all $T, T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \sim^{\mathcal{I}, \mathcal{A}} T' \quad \text{iff} \quad \Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T'),$$

i.e., $\sim^{\mathcal{I}, \mathcal{A}}$ is the kernel of the Leibniz operator on $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$.

It is clear from the definition that $\sim^{\mathcal{I}, \mathcal{A}}$ is an equivalence relation on $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$. In case $\mathcal{I}$ is protoalgebraic, we have another important property.

Lemma 1502 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. If $\mathcal{I}$ is protoalgebraic, then each equivalence class of $\sim^{\mathcal{I}, \mathcal{A}}$ has a minimum element.*

Proof: Let $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and consider the equivalence class $[T]$ of T under $\sim^{\mathcal{I}, \mathcal{A}}$. Then we have $\cap[T] \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, moreover,

$$\begin{aligned} \Omega^{\mathcal{A}}(\cap[T]) &= \cap\{\Omega^{\mathcal{A}}(T'); T' \in [T]\} \\ &= \cap\{\Omega^{\mathcal{A}}(T) : T' \in [T]\} \\ &= \Omega^{\mathcal{A}}(T). \end{aligned}$$

So $\cap[T] \in [T]$ and, therefore, $\cap[T]$ is the minimum element of $[T]$. ■

The next proposition provides the promised characterization of those $\mathcal{I}$ -filter families that determine full $\mathcal{I}$ -structures through their principal filters in $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, in the case of a protoalgebraic $\mathcal{I}$.

Proposition 1503 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a protoalgebraic π -institution based on $\mathbf{F}$. For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and every $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, the following conditions are equivalent:*

- (i) $T \in \mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A})$, i.e., $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \mathbf{FStr}(\mathcal{I})$;
- (ii) $T = \min[T]$, where $[T]$ is the equivalence class of T under $\sim^{\mathcal{I}, \mathcal{A}}$;

$$(iii) \quad T/\Omega^{\mathcal{A}}(T) = \min \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T)).$$

Proof:

(ii) $\Rightarrow$ (iii) Assume that $T = \min[T]$ and let $Y \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. Our goal is to show that $T/\Omega^{\mathcal{A}}(T) \leq Y$. Consider the quotient morphism $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T)$ and let $X = \pi^{-1}(Y) \cap T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then

$$X = \pi^{-1}(Y) \cap \pi^{-1}(\pi(T)) = \pi^{-1}(Y \cap \pi(T)).$$

It follows that $\Omega^{\mathcal{A}}(T)$ is compatible with X and, hence, $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(X)$. But, by definition, $X \leq T$ and, thus, by protoalgebraicity, $\Omega^{\mathcal{A}}(X) \leq \Omega^{\mathcal{A}}(T)$. We conclude that $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(X)$ and, hence, $T \sim^{\mathcal{I}, \mathcal{A}} X$. By hypothesis, we now get $T \leq \pi^{-1}(Y)$, i.e., $T/\Omega^{\mathcal{A}}(T) \leq X$. Since $Y \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$ was arbitrary, we conclude that $T/\Omega^{\mathcal{A}}(T) = \min \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$.

(iii) $\Rightarrow$ (i) Suppose that $T/\Omega^{\mathcal{A}}(T) = \min \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$. By protoalgebraicity (see the Correspondence Theorem 1373),

$$\pi : \mathbf{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T \rangle) \cong \mathbf{FiFam}^{\mathcal{I}}(\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle).$$

By hypothesis,

$$\text{FiFam}^{\mathcal{I}}(\langle \mathcal{A}/\Omega^{\mathcal{A}}(T), T/\Omega^{\mathcal{A}}(T) \rangle) = \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T)).$$

Since, by Proposition 1497, $\tilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T \rangle)) = \Omega^{\mathcal{A}}(T)$, we obtain

$$\text{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T \rangle)^* = \text{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T \rangle^*).$$

This proves that $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\langle \mathcal{A}, T \rangle) \rangle$ is a full $\mathcal{I}$ -structure. We conclude that $T \in \text{FiFam}^{\mathcal{I}, f}(\mathcal{A})$.

(i) $\Rightarrow$ (ii) Suppose $T \in \text{FiFam}^{\mathcal{I}, f}(\mathcal{A})$. Since $\mathcal{I}$ is protoalgebraic, by Lemma 1502, there exists $T' = \min[T]$. By the proofs of the two preceding implications (ii) $\Rightarrow$ (iii) $\Rightarrow$ (i), $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'} \rangle$ is a full $\mathcal{I}$ -structure. But, by hypothesis, $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is also a full $\mathcal{I}$ -structure. Now observe that, by Proposition 1497,

$$\tilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'}) = \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T).$$

By the Isomorphism Theorem 1445, $\text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T'} = \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ and, therefore, $T' = T$. So we conclude that $T = \min[T]$. ■

Since, for a protoalgebraic π -institution $\mathcal{I}$, the filter families determining full $\mathcal{I}$ -structures are the ones that are minimal in their equivalence classes under $\sim^{\mathcal{I}, \mathcal{A}}$, we can easily conclude that the class of those filter families consists of all filter families just in case all equivalence classes are singletons.

Proposition 1504 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Then $\mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A}) = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ (i.e., for all $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is a full $\mathcal{I}$ -structure) if and only if $\Omega^{\mathcal{A}}$ is injective on $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$.*

Proof: By Proposition 1503, $\mathbf{FiFam}^{\mathcal{I},f}(\mathcal{A}) = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ if and only if, for all $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T = \min[T]$, if and only if, for all $T, T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(T')$ implies $T = T'$, if and only if $\Omega^{\mathcal{A}}$ is injective on $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Recall that a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is called **weakly family algebraizable**, or **WF algebraizable** for short, if the Leibniz operator Ω is monotone and injective on the theory families of $\mathcal{I}$. Equivalently, by Theorem 295, $\mathcal{I}$ is WF algebraizable if and only if, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$, the Leibniz operator on $\mathcal{A}$ is monotone and injective on $\mathcal{I}$ -filter families.

The following theorem provides additional characterizations in terms of $\mathcal{I}$ -structures and $\mathcal{I}$ -congruence systems.

Theorem 1505 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Then the following conditions are equivalent.*

- (i) $\mathcal{I}$ is protoalgebraic and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, $T/\Omega^{\mathcal{A}}(T) = \min \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))$;
- (ii) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is monotone and injective on $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$;
- (iii) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $T \mapsto \langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is a bijection between $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$ and, hence, an order isomorphism from $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ to $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$;
- (iv) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$ is an order isomorphism;
- (v) For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$ is an order isomorphism.

Proof:

(i) $\Leftrightarrow$ (ii) By Propositions 1503 and 1504.

(i) $\Rightarrow$ (iii) It is clear that $T \mapsto \langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$ is injective. By Proposition 1503, it is into $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$ and, by Theorem 1500, it is onto $\mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$. Hence it is a bijection, as claimed.

- (iii) $\Rightarrow$ (iv) Since, by hypothesis, every full $\mathcal{I}$ -structure is of the form $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle$, by Theorem 1500, $\mathcal{I}$ is protoalgebraic. The composition of the given isomorphism

$$\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \cong \mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$$

with the isomorphism established in the Isomorphism Theorem 1445,

$$\tilde{\Omega}^{\mathcal{A}} : \mathbf{FStr}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$$

gives an isomorphism

$$\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \cong \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}),$$

which by protoalgebraicity and Proposition 1497 is identical to the Leibniz operator.

- (iv) $\Rightarrow$ (v) By Corollary 1442, $\mathbf{AlgSys}^*(\mathcal{I}) \subseteq \mathbf{AlgSys}(\mathcal{I})$. Thus, $\mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A}) \subseteq \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$. By the hypothesis, every $\theta \in \mathbf{ConSys}^{\mathcal{I}}(\mathcal{A})$ is of the form $\Omega^{\mathcal{A}}(T)$, for some $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, $\mathbf{ConSys}^{\mathcal{I}}(\mathcal{A}) \subseteq \mathbf{ConSys}^{\mathcal{I}*}(\mathcal{A})$.

- (v) $\Rightarrow$ (ii) is trivial. ■

In the context of weakly family algebraizable π -institutions, we look, also at the local continuity of the Leibniz and the Tarski operators.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system.

- $\Omega^{\mathcal{A}}$ is **continuous** if, for every directed collection $\{T^i : i \in I\} \subseteq \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcup_{i \in I} T^i \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have

$$\Omega^{\mathcal{A}}\left(\bigcup_{i \in I} T^i\right) = \bigcup_{i \in I} \Omega^{\mathcal{A}}(T^i).$$

- $\tilde{\Omega}^{\mathcal{A}}$ is **continuous** if, for every directed family $\{\mathbb{L}^i : i \in I\} \subseteq \mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$,

$$\tilde{\Omega}^{\mathcal{A}}(\sup\{\mathbb{L}^i : i \in I\}) = \bigcup_{i \in I} \tilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i).$$

Proposition 1506 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is weakly family algebraizable, then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Omega^{\mathcal{A}}$ is continuous if and only if $\tilde{\Omega}^{\mathcal{A}}$ is continuous.*

Proof: Let $\Phi : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{FStr}^{\mathcal{I}}(\mathcal{A})$ be the bijection of Theorem 1505. Then, by Proposition 1497,

$$\Omega^{\mathcal{A}} = \tilde{\Omega}^{\mathcal{A}} \circ \Phi \quad \text{and} \quad \tilde{\Omega}^{\mathcal{A}} = \Omega^{\mathcal{A}} \circ \Phi^{-1}.$$

Suppose, first, that $\Omega^{\mathcal{A}}$ is continuous and let $\{\mathbb{L}^i : i \in I\} \subseteq \text{FStr}^{\mathcal{I}}(\mathcal{A})$ be directed. If $T^i = \Phi^{-1}(\mathbb{L}^i)$, $i \in I$, then $\{T^i : i \in I\} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is also directed. Directedness implies local directedness and, therefore, by Proposition 112, $\bigcup_{i \in I} T^i \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Now we get

$$\Phi\left(\bigcup_{i \in I} T^i\right) = \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{\bigcup_{i \in I} T^i} \rangle = \langle \mathcal{A}, \bigcap_{i \in I} \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^i} \rangle,$$

whence $\Phi(\bigcup_{i \in I} T^i) = \sup_{i \in I} \mathbb{L}^i$. Therefore, we get

$$\tilde{\Omega}^{\mathcal{A}}(\sup_{i \in I} \mathbb{L}^i) = (\Omega^{\mathcal{A}} \circ \Phi^{-1})(\Phi(\bigcup_{i \in I} T^i)) = \Omega^{\mathcal{A}}(\bigcup_{i \in I} T^i) = \bigcup_{i \in I} \Omega^{\mathcal{A}}(T^i) = \bigcup_{i \in I} \tilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i).$$

So $\tilde{\Omega}^{\mathcal{A}}$ is also continuous.

Assume, conversely, $\tilde{\Omega}^{\mathcal{A}}$ is continuous. Let $\{T^i : i \in I\} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ be directed. Then $\{\Phi(T^i) : i \in I\} \subseteq \text{FStr}^{\mathcal{I}}(\mathcal{A})$ is also directed and we have

$$\Omega^{\mathcal{A}}(\bigcup_{i \in I} T^i) = \tilde{\Omega}^{\mathcal{A}}(\Phi(\bigcup_{i \in I} T^i)) = \tilde{\Omega}^{\mathcal{A}}(\sup_{i \in I} \mathbb{L}^i) = \bigcup_{i \in I} \tilde{\Omega}^{\mathcal{A}}(\mathbb{L}^i) = \bigcup_{i \in I} \Omega^{\mathcal{A}}(T^i).$$

Therefore $\Omega^{\mathcal{A}}$ is also continuous. ■

19.11 $\mathcal{I}$ -Structures and Fregeanity

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. $\mathcal{I}$ is called **Fregean** if, for all $T \in \text{ThFam}(\mathcal{I})$, the π -structure $\mathcal{I}^T$ has the Congruence Property, i.e., for all $T \in \text{ThFam}(\mathcal{I})$,

$$\tilde{\Lambda}^{\mathcal{I}}(T) = \tilde{\Omega}^{\mathcal{I}}(T).$$

Clearly, $\mathcal{I}$ is Fregean if, for all $T \in \text{ThFam}(\mathcal{I})$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, if, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$C_{\Sigma'}(T_{\Sigma'}, \text{SEN}^b(f)(\phi)) = C_{\Sigma'}(T_{\Sigma'}, \text{SEN}^b(f)(\psi)),$$

then, for all σ^b in N^b , all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\tilde{\chi} \in \text{SEN}^b(\Sigma')$,

$$C_{\Sigma'}(T_{\Sigma'}, \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\phi), \tilde{\chi})) = C_{\Sigma'}(T_{\Sigma'}, \sigma_{\Sigma'}^b(\text{SEN}^b(f)(\psi), \tilde{\chi})).$$

$\mathcal{I}$ is called **strongly Fregean** if, for all $T \in \text{ThFam}(\mathcal{I})$, the π -structure $\mathcal{I}^T$ has the strong Congruence Property, i.e., for all $T \in \text{ThFam}(\mathcal{I})$,

$$\tilde{\chi}^{\mathcal{I}}(T) = \tilde{\Omega}^{\mathcal{I}}(T).$$

In this case, we get that $\mathcal{I}$ is strongly Fregean if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$C_{\Sigma}(T_{\Sigma}, \phi) = C_{\Sigma}(T_{\Sigma}, \psi)$$

implies, for all σ^b in N^b , all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$,

$$C_{\Sigma'}(T_{\Sigma'}, \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \vec{\chi})) = C_{\Sigma'}(T_{\Sigma'}, \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \vec{\chi})).$$

A consequence of strong Fregeanity is that every reduced matrix family model has either an empty filter family or a filter family all of whose components are singletons.

Proposition 1507 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly Fregean, then, for every reduced $\mathcal{I}$ -matrix family $\mathfrak{A} = \langle \mathcal{A}, T \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathbf{A} = \langle \mathbf{Sign}, \mathbf{SEN}, N \rangle$, we have, for all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 0$, or, for all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 1$.*

We abbreviate the first disjunct of the conclusion, as usual, by $T = \emptyset$ and the second by writing $|T| = 1$.

Proof: Assume that $T \neq \emptyset$ and let $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \in T_{F(\Sigma)}$. Then $\phi, \psi \in \alpha_\Sigma^{-1}(T_{F(\Sigma)})$. Hence,

$$C_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)}), \phi) = C_\Sigma(\alpha_\Sigma^{-1}(T_{F(\Sigma)}), \psi),$$

i.e., $\langle \phi, \psi \rangle \in \tilde{\lambda}_\Sigma^T(\alpha^{-1}(T))$. By strong Fregeanity, $\langle \phi, \psi \rangle \in \tilde{\Omega}_\Sigma^T(\alpha^{-1}(T))$. Thus, for all σ^b in N^b , all $\Sigma' \in |\mathbf{Sign}^b|$, all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$ and all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma')$,

$$\begin{aligned} C_{\Sigma'}(\alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}), \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \vec{\chi})) \\ = C_{\Sigma'}(\alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}), \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \vec{\chi})). \end{aligned}$$

Now we get

$$\sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\phi), \vec{\chi}) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}) \quad \text{iff} \quad \sigma_{\Sigma'}^b(\mathbf{SEN}^b(f)(\psi), \vec{\chi}) \in \alpha_{\Sigma'}^{-1}(T_{F(\Sigma')}).$$

Equivalently,

$$\begin{aligned} \sigma_{F(\Sigma')}(\mathbf{SEN}(F(f))(\alpha_\Sigma(\phi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')} \\ \text{iff} \quad \sigma_{F(\Sigma')}(\mathbf{SEN}(F(f))(\alpha_\Sigma(\psi)), \alpha_{\Sigma'}(\vec{\chi})) \in T_{F(\Sigma')}. \end{aligned}$$

Taking into account the surjectivity of $\langle F, \alpha \rangle$, we get that $\langle \alpha_\Sigma(\phi), \alpha_\Sigma(\psi) \rangle \in \Omega_{F(\Sigma)}^A(T) = \Delta_{F(\Sigma)}^A$, the last equation holding since $\mathfrak{A}$ is reduced. Hence, $\alpha_\Sigma(\phi) = \alpha_\Sigma(\psi)$ and, therefore, for all $\Sigma \in |\mathbf{Sign}|$, $|T_\Sigma| = 1$. ■

Of course, in the case of Fregeanity and protoalgebraicity, the role of the Tarski operator may be substituted by the Leibniz operator.

Proposition 1508 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$.*

- (a) $\mathcal{I}$ is protoalgebraic and Fregean if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \tilde{\Lambda}^{\mathcal{I}}(T)$;
- (b) $\mathcal{I}$ is protoalgebraic and strongly Fregean if and only if, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \tilde{\lambda}^{\mathcal{I}}(T)$.

Proof: We only prove Part (a), since Part (b) can be proven by following a similar reasoning.

If $\mathcal{I}$ is protoalgebraic, then, by Proposition 1497, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \tilde{\Omega}^{\mathcal{I}}(T)$. If $\mathcal{I}$ is Fregean, then, by definition, for all $T \in \text{ThFam}(\mathcal{I})$, $\tilde{\Omega}^{\mathcal{I}}(T) = \tilde{\Lambda}^{\mathcal{I}}(T)$. Therefore, if $\mathcal{I}$ is protoalgebraic and Fregean, then, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \tilde{\Lambda}^{\mathcal{I}}(T)$.

Assume, conversely, that, for all $T \in \text{ThFam}(\mathcal{I})$, we have $\Omega(T) = \tilde{\Lambda}^{\mathcal{I}}(T)$. Then, for all $T, T' \in \text{ThFam}(\mathcal{I})$, such that $T \leq T'$, we have

$$\Omega(T) = \tilde{\Lambda}^{\mathcal{I}}(T) \stackrel{\text{Lemma 1453}}{\leq} \tilde{\Lambda}^{\mathcal{I}}(T') = \Omega(T').$$

Thus, Ω is monotone on $\text{ThFam}(\mathcal{I})$ and $\mathcal{I}$ is protoalgebraic. Moreover, since, by Proposition 1497, for all $T \in \text{ThFam}(\mathcal{I})$, $\tilde{\Omega}^{\mathcal{I}}(T) = \Omega(T)$, we get $\tilde{\Omega}^{\mathcal{I}}(T) = \tilde{\Lambda}^{\mathcal{I}}(T)$ and, therefore, $\mathcal{I}$ is also Fregean. ■

Recall that a π -institution $\mathcal{I}$ is self extensional if

$$\tilde{\Omega}(\mathcal{I}) = \tilde{\Lambda}(\mathcal{I}) (= \tilde{\lambda}(\mathcal{I})).$$

It turns out that Fregeanity (and, therefore, strong Fregeanity) implies self extensionality.

Corollary 1509 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is Fregean, then it is self extensional.*

Proof: We have

$$\begin{aligned} \tilde{\Omega}(\mathcal{I}) &= \tilde{\Omega}^{\mathcal{I}}(\text{Thm}(\mathcal{I})) \quad (\text{by definition}) \\ &= \tilde{\Lambda}^{\mathcal{I}}(\text{Thm}(\mathcal{I})) \quad (\text{by Fregeanity}) \\ &= \tilde{\Lambda}(\mathcal{I}). \quad (\text{by definition}) \end{aligned}$$

So $\mathcal{I}$ is self extensional. ■

If a π -institution $\mathcal{I}$ is strongly Fregean and has theorems, then the mapping $T \mapsto \mathcal{I}^T$ establishes an order embedding from the lattice of the theory families of $\mathcal{I}$ into the lattice of full $\mathcal{I}$ -structures on the algebraic system $\mathcal{F}$.

Proposition 1510 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly Fregean with theorems, then $T \mapsto \mathcal{I}^T$ is an order embedding of $\text{ThFam}(\mathcal{I})$ into $\mathbf{FStr}^{\mathcal{I}}(\mathcal{F})$.*

Proof: We start by showing that the proposed mapping is indeed well-defined into $\mathbf{FStr}^{\mathcal{I}}(\mathcal{F})$, i.e., that, for all $T \in \mathbf{ThFam}(\mathcal{I})$, $\mathcal{I}^T = \langle \mathcal{F}, \mathbf{ThFam}(\mathcal{I})^T \rangle$ is a full $\mathcal{I}$ -structure. To this end, let $T \in \mathbf{ThFam}(\mathcal{I})$ and set $\theta = \tilde{\Omega}^{\mathcal{I}}(T) = \tilde{\lambda}^{\mathcal{I}}(T)$. To verify that $\mathcal{I}^T$ is a full $\mathcal{I}$ -structure, it suffices to show that $\mathbf{ThFam}(\mathcal{I}^T)/\theta = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$.

If $T' \in \mathbf{ThFam}(\mathcal{I}^T)$, then, by definition of θ , θ is compatible with T' . Therefore, by Corollary 56, $T'/\theta \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$. Thus, $\mathbf{ThFam}(\mathcal{I}^T)/\theta \subseteq \mathbf{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$.

If, on the other hand, $T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta)$, then, setting $\langle I, \pi \rangle : \mathcal{F} \rightarrow \mathcal{F}/\theta$ the quotient morphism, we have, by Corollary 55, $\pi^{-1}(T') \in \mathbf{Fifam}^{\mathcal{I}}(\mathcal{F})$, i.e., $\pi^{-1}(T') \in \mathbf{ThFam}(\mathcal{I})$. We also have, taking into account that $\mathcal{I}$ has theorems, that, for all $\Sigma \in |\mathbf{Sign}^b|$, all $\phi \in T_{\Sigma}$ and $\psi \in T_{\Sigma} \cap \pi_{\Sigma}^{-1}(T'_{\Sigma})$,

$$\langle \phi, \psi \rangle \in \tilde{\lambda}_{\Sigma}^{\mathcal{I}}(T) = \theta_{\Sigma}.$$

So $\pi_{\Sigma}(\phi) = \pi_{\Sigma}(\psi)$, whence $\phi \in \pi_{\Sigma}^{-1}(\pi_{\Sigma}(\psi)) \in \pi_{\Sigma}^{-1}(T'_{\Sigma})$. Since $\phi \in T_{\Sigma}$ was arbitrary, $T \leq \pi^{-1}(T')$ and, hence, $\pi^{-1}(T') \in \mathbf{ThFam}(\mathcal{I}^T)$. This shows that $T' \in \mathbf{ThFam}(\mathcal{I}^T)/\theta$ and allows us to conclude that $\mathbf{FiFam}^{\mathcal{I}}(\mathcal{F}/\theta) \subseteq \mathbf{ThFam}(\mathcal{I}^T)/\theta$.

As for the rest, everything follows, since $T \mapsto \mathcal{I}^T$ is clearly one-to-one and both order preserving and order reflecting. ■

If one adds protoalgebraicity into the mix, then the order embedding of Proposition 1510 becomes an order isomorphism.

Proposition 1511 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a strongly Fregean protoalgebraic π -institution with theorems, based on $\mathbf{F}$. Then $T \mapsto \mathcal{I}^T$ is an isomorphism between $\mathbf{ThFam}(\mathcal{I})$ and $\mathbf{FStr}^{\mathcal{I}}(\mathcal{F})$.*

Proof: By Proposition 1510, it suffices to show that the mapping $T \mapsto \mathcal{I}^T$ is also onto $\mathbf{FStr}^{\mathcal{I}}(\mathcal{F})$. The latter follows from Theorem 1500. ■

Strong Fregeanity, protoalgebraicity and the existence of theorems have very strong consequences for a π -institution. They ensure that the π -institution is weakly family algebraizable, that the Leibniz operator is continuous (in case of finitariness) and that all reduced matrix families have singleton filter families.

Proposition 1512 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a strongly Fregean protoalgebraic π -institution with theorems.*

- (a) $\mathcal{I}$ is family injective and hence weakly family algebraizable;
- (b) If $\mathcal{I}$ is finitary, then Ω is locally continuous;
- (c) For every $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \mathbf{MatFam}^*(\mathcal{I})$, $|T| = 1$.

Proof: By Proposition 1497, for all $T \in \text{ThFam}(\mathcal{I})$, $\Omega(T) = \tilde{\Omega}^{\mathcal{I}}(T)$. Thus, composing the mapping $T \mapsto \mathcal{I}^T$ of Proposition 1511, with the isomorphism of Theorem 1445, we obtain an isomorphism $\Omega : \mathbf{ThFam}(\mathcal{I}) \rightarrow \mathbf{ConSys}^{\mathcal{I}}(\mathcal{F})$. By Proposition 1508, $\Omega = \tilde{\lambda}^{\mathcal{I}}$ and, hence, by Proposition 1456, Ω is locally continuous. Finally, if $\mathfrak{A} = \langle \mathcal{A}, T \rangle \in \text{MatFam}^*(\mathcal{I})$, then, since $\mathcal{I}$ has theorems, $T \neq \emptyset$ and, therefore, by Proposition 1507, $|T| = 1$. ■

We saw in Corollary 1509 that Fregeanity implies self extensionality. On the other hand, even though we cannot prove that strong Fregeanity, coupled with protoalgebraicity, are strong enough to guarantee full self extensionality, we can show that they imply a weaker property, namely a version of full self extensionality applying only to full $\mathcal{I}$ -structures with isomorphic functor components. We start with a technical lemma.

Lemma 1513 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a strongly Fregean protoalgebraic π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system, with $F : \mathbf{Sign}^b \rightarrow \mathbf{Sign}$ an isomorphism. Then, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\Omega^{\mathcal{A}}(T) = \tilde{\lambda}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T).$$

Proof: Note that, by protoalgebraicity, $\Omega^{\mathcal{A}}(T) = \tilde{\Omega}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. Therefore, by compatibility, $\Omega^{\mathcal{A}}(T) \leq \tilde{\lambda}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. It therefore suffices to show the reverse inclusion. To this end and taking into account the surjectivity of $\langle F, \alpha \rangle$, let $\Sigma \in |\mathbf{Sign}^b|$ and $\phi, \psi \in \text{SEN}^b(\Sigma)$, such that $\langle \alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi) \rangle \in \tilde{\lambda}_{F(\Sigma)}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T)$. Then, by definition, for all $T \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, we have

$$\alpha_{\Sigma}(\phi) \in T''_{F(\Sigma)} \quad \text{iff} \quad \alpha_{\Sigma}(\psi) \in T''_{F(\Sigma)}.$$

However, since $\mathcal{I}$ is protoalgebraic, we get, by the Correspondence Theorem 1373, that, for all $\alpha^{-1}(T) \leq T' \in \text{ThFam}(\mathcal{I})$,

$$\phi \in T'_{\Sigma} \quad \text{iff} \quad \psi \in T'_{\Sigma}.$$

Hence, by definition,

$$\begin{aligned} \langle \phi, \psi \rangle &\in \tilde{\lambda}_{\Sigma}^{\mathcal{I}}(\alpha^{-1}(T)) \\ &= \Omega_{\Sigma}(\alpha^{-1}(T)) \quad (\text{strong Fregeanity}) \\ &= \alpha_{\Sigma}^{-1}(\Omega_{F(\Sigma)}^{\mathcal{A}}(T)). \quad (\text{Proposition 24}) \end{aligned}$$

Hence $\langle \alpha_{\Sigma}(\phi), \alpha_{\Sigma}(\psi) \rangle \in \Omega_{F(\Sigma)}^{\mathcal{A}}(T)$. Taking into account the surjectivity of $\langle F, \alpha \rangle$, we now conclude that $\tilde{\lambda}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T) \leq \Omega^{\mathcal{A}}(T)$. ■

Proposition 1514 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\mathcal{I}$ is strongly Fregean and protoalgebraic, then, every full $\mathcal{I}$ -structure, with an isomorphic functor component, has the Congruence Property.*

Proof: We deal first with the case $\text{Thm}(\mathcal{I}) = \emptyset$. Then, since $\mathcal{I}$ is protoalgebraic, the only option is

$$\text{ThFam}(\mathcal{I}) = \{T : T_\Sigma = \emptyset \text{ or } \text{SEN}^b(\Sigma), \text{ for all } \Sigma \in |\mathbf{Sign}^b|\}.$$

In this case, given an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the only full $\mathcal{I}$ -structures on $\mathcal{A}$ are of the form $\langle \mathcal{A}, \mathcal{D} \rangle$, with

$$\mathcal{D} = \{T : T_\Sigma = \emptyset \text{ or } \text{SEN}(\Sigma), \text{ for all } \Sigma \in |\mathbf{Sign}|\}.$$

All those have the Congruence Property.

Assume, next, that $\mathcal{I}$ has theorems. By Lemma 1513, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with $F : \mathbf{Sign}^b \rightarrow \mathbf{Sign}$ an isomorphism, and every $T \in \text{FiFam}^\mathcal{I}(\mathcal{A})$,

$$\Omega^\mathcal{A}(T) = \widetilde{\lambda}^\mathcal{A}(\text{FiFam}^\mathcal{I}(\mathcal{A})^T).$$

Thus, $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A})^T \rangle$ has the strong Congruence Property. Since, by Theorem 1500, every full $\mathcal{I}$ -structure, with an isomorphic functor component has this form, we conclude that every full $\mathcal{I}$ -structure, with an isomorphic functor component, has the Congruence Property. ■

For finitary fully self extensional π -institutions, we obtain the following characterizations of weak family algebraizability.

Proposition 1515 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary, fully self extensional π -institution based on $\mathbf{F}$. Then the following conditions are equivalent.*

- (i) $\mathcal{I}$ is strongly Fregean, protoalgebraic and has theorems;
- (ii) $\mathcal{I}$ is weakly family algebraizable and Ω is locally continuous;
- (iii) $\mathcal{I}$ is weakly family algebraizable.

Proof: (i) $\Rightarrow$ (ii) follows from Proposition 1512. (ii) $\Rightarrow$ (iii) is trivial. For (iii) $\Rightarrow$ (i) note, first, that, by hypothesis $\mathcal{I}$ is family monotone and family injective. Thus, $\mathcal{I}$ is protoalgebraic. By Proposition 1505, for all $T \in \text{ThFam}(\mathcal{I})$, $\mathcal{I}^T \in \text{FStr}^\mathcal{I}(\mathcal{F})$. Hence, by full self extensionality, $\mathcal{I}^T$ has the strong Congruence Property and, hence, $\mathcal{I}$ is strongly Fregean. Finally, since $\Omega(\emptyset) = \Omega(\text{SEN}^b) = \nabla^\mathcal{F}$, we get, by injectivity, $\emptyset \notin \text{ThFam}(\mathcal{I})$ and $\mathcal{I}$ has theorems. ■

Chapter 20

Full Adequacy

20.1 Gentzen π -Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\Sigma \in |\mathbf{Sign}^b|$. A Σ -**sequent** is a pair

$$\langle \Phi, \phi \rangle,$$

where $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$ (with Φ possibly empty). Sometimes we write

$$\Phi \triangleright_{\Sigma} \phi \quad \text{or} \quad \Phi \vdash_{\Sigma} \phi$$

to denote the Σ -sequent $\langle \Phi, \phi \rangle$. The set Φ is called **set of antecedents** of $\langle \Phi, \phi \rangle$ and ϕ is called the **consequent** of $\langle \Phi, \phi \rangle$.

The collection of Σ -sequents is denoted by $\text{Seq}_{\Sigma}(\mathbf{F})$ and the set of all Σ -sequents with nonempty set of antecedents is denoted by $\text{Seq}_{\Sigma}^0(\mathbf{F})$. We then set

$$\text{Seq}(\mathbf{F}) = \{\text{Seq}_{\Sigma}(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^b|} \quad \text{and} \quad \text{Seq}^0(\mathbf{F}) = \{\text{Seq}_{\Sigma}^0(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^b|}.$$

We sometimes use boldface Greek letters such as $\gamma, \delta, \dots$ to denote Σ -sequents and boldface capital Greek letters such as $\Gamma, \Delta, \dots$ for sets of Σ -sequents. Moreover, we write $\Gamma \vdash_{\Sigma} \Phi$ to stand for the set $\{\Gamma \vdash_{\Sigma} \phi : \phi \in \Phi\}$ of Σ -sequents.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system. A **Gentzen π -institution based on $\mathbf{F}$ of type 1 (of type 0, respectively)** is a pair

$$\mathfrak{G} = \langle \mathbf{F}, G \rangle,$$

where $G : \mathcal{P}(\text{Seq}(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}(\mathbf{F}))$ ($G : \mathcal{P}(\text{Seq}^0(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}^0(\mathbf{F}))$, respectively) is a closure system on $\text{Seq}(\mathbf{F})$ ($\text{Seq}^0(\mathbf{F})$, respectively) that, in addition, satisfies the following **structural rules**, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \Psi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$:

$$\begin{aligned} (\text{Axiom}) \quad & \phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\emptyset); \\ (\text{Weakening}) \quad & \Phi, \Psi \vdash_{\Sigma} \phi \in G_{\Sigma}(\Phi \vdash_{\Sigma} \phi); \\ (\text{Cut}) \quad & \Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\Phi \vdash_{\Sigma} \Psi, \Phi, \Psi \vdash_{\Sigma} \phi). \end{aligned}$$

If $\Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\emptyset)$ we call $\Phi \vdash_{\Sigma} \phi$ a Σ -**theorem** or a **derivable Σ -sequent** of $\mathfrak{G}$.

Each Gentzen π -institution based on an algebraic system $\mathbf{F}$ defines in a natural way a π -institution based on $\mathbf{F}$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. The π -**institution** $\mathcal{I}^{\mathfrak{G}} = \langle F, C^{\mathfrak{G}} \rangle$ **defined** or **determined by $\mathfrak{G}$** is defined by setting, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$,

$$\phi \in C_{\Sigma}^{\mathfrak{G}}(\Phi) \quad \text{iff} \quad \Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\emptyset).$$

Proposition 1516 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. $C^\mathfrak{G} : \mathcal{P}\text{SEN}^b \rightarrow \mathcal{P}\text{SEN}^b$ is a closure system on SEN^b and, hence, $\mathcal{I}^\mathfrak{G} = \langle \mathbf{F}, C^\mathfrak{G} \rangle$ is a π -institution.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \Psi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$.

If $\phi \in \Phi$, then, by (Axiom) $\phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$ and by (Weakening) $\Phi \vdash_\Sigma \phi \in G_\Sigma(\phi \vdash_\Sigma \phi)$, whence $\Phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$. Therefore $\phi \in C_\Sigma^\mathfrak{G}(\Phi)$.

If $\Phi \subseteq \Psi$ and $\phi \in C_\Sigma^\mathfrak{G}(\Phi)$, then $\Phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$ and, by (Weakening), $\Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi)$, whence $\Psi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$, giving $\phi \in C_\Sigma^\mathfrak{G}(\Psi)$.

If $\phi \in C_\Sigma^\mathfrak{G}(C_\Sigma^\mathfrak{G}(\Phi))$, then $C_\Sigma^\mathfrak{G}(\Phi) \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$ and, by (Weakening),

$$\Phi, C_\Sigma^\mathfrak{G}(\Phi) \vdash_\Sigma \phi \in G_\Sigma(C_\Sigma^\mathfrak{G}(\Phi) \vdash_\Sigma \phi) \subseteq G_\Sigma(\emptyset).$$

Moreover, by definition $\Phi \vdash_\Sigma C_\Sigma^\mathfrak{G}(\Phi) \subseteq G_\Sigma(\emptyset)$, whence, by (Cut),

$$\Phi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma C_\Sigma^\mathfrak{G}(\Phi), \Phi, C_\Sigma^\mathfrak{G}(\Phi) \vdash_\Sigma \phi) \subseteq G_\Sigma(\emptyset).$$

Therefore, $\phi \in C_\Sigma^\mathfrak{G}(\Phi)$.

Finally, suppose $\phi \in C_\Sigma^\mathfrak{G}(\Phi)$, $\Sigma' \in |\mathbf{Sign}^b|$ and $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$. Then, by definition, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$ and, by structurality,

$$\text{SEN}^b(f)(\Phi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in G_{\Sigma'}(\emptyset).$$

This shows that $\text{SEN}^b(f)(\phi) \in C_{\Sigma'}^\mathfrak{G}(\text{SEN}^b(f)(\Phi))$ and, therefore, $C^\mathfrak{G}$ is a closure system on SEN^b , as was to be shown. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution, also based on $\mathbf{F}$. We say that $\mathfrak{G}$ is **adequate for $\mathcal{I}$** if $C = C^\mathfrak{G}$ and, moreover,

- $\mathfrak{G}$ is of type 1 if $\mathcal{I}$ has theorems and
- $\mathfrak{G}$ is of type 0 if $\mathcal{I}$ does not have theorems.

The following proposition clarifies the distinction imposed on the type, since it reveals the fact that, if $\mathcal{I}$ has no theorems, then it is sufficient to assume that a Gentzen π -institution adequate for $\mathcal{I}$ has type 0.

Proposition 1517 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$.*

- (a) *If $\mathfrak{G}$ is of type 0, then $\mathcal{I}^\mathfrak{G}$ does not have theorems.*
- (b) *If $\mathfrak{G}$ is of type 1, then its restriction $\mathfrak{G}^0 = \langle \mathbf{F}, G^0 \rangle$ to $\text{Seq}^0(\mathbf{F})$ is a Gentzen π -institution of type 0.*
- (c) *If $\mathfrak{G}$ is of type 1 and $\mathcal{I}^\mathfrak{G}$ has no theorems, then $\mathcal{I}^\mathfrak{G} = \mathcal{I}^{\mathfrak{G}^0}$.*

Proof:

- (a) Suppose $\mathcal{I}^\mathfrak{G}$ has theorems. Thus, for all $\Sigma \in |\mathbf{Sign}^b|$, there exists $\phi \in \text{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma^\mathfrak{G}(\emptyset)$. Thus, by definition, $\emptyset \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$. Therefore, $\mathfrak{G}$ cannot be of type 0 (since it admits a sequent with an empty set of antecedents).
- (b) Suppose $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ is of type 1. Consider $\mathfrak{G}^0 = \langle \mathbf{F}, G^0 \rangle$. We must show that $G^0 : \mathcal{P}(\text{Seq}^0(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}^0(\mathbf{F}))$ is a closure system on $\text{Seq}^0(\mathbf{F})$ that satisfies the structural rules.
- Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma^0(\mathbf{F})$, such that $\gamma \in \Gamma$. Then $\gamma \in G_\Sigma(\Gamma)$ and, hence, $\gamma \in G_\Sigma^0(\Gamma)$.
 - Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \Delta \cup \{\gamma\} \subseteq \text{Seq}_\Sigma^0(\mathbf{F})$, such that $\gamma \in G_\Sigma^0(\Gamma)$ and $\Gamma \subseteq \Delta$. Then, by definition, $\gamma \in G_\Sigma(\Gamma)$ and $\Gamma \subseteq \Delta$, whence $\gamma \in G_\Sigma(\Delta)$. So $\gamma \in G_\Sigma^0(\Delta)$.
 - Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma^0(\mathbf{F})$, such that $\gamma \in G_\Sigma^0(G_\Sigma^0(\Gamma))$. Then $\gamma \in G_\Sigma(G_\Sigma(\Gamma)) = G_\Sigma(\Gamma)$. As $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma^0(\mathbf{F})$, it follows that $\gamma \in G_\Sigma^0(\Gamma)$.
 - Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma^0(\mathbf{F})$, such that $\gamma \in G_\Sigma^0(\Gamma)$, $\Sigma' \in |\mathbf{Sign}^b|$ and $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$. Then $\gamma \in G_\Sigma(\Gamma)$, whence $\text{SEN}^b(f)(\gamma) \in G_{\Sigma'}(\text{SEN}^b(f)(\Gamma))$. Observing that, if $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma^0(\mathbf{F})$, then $\text{SEN}^b(f)(\Gamma) \cup \{\text{SEN}^b(f)(\gamma)\} \subseteq \text{Seq}_{\Sigma'}^0(\mathbf{F})$, we conclude that

$$\text{SEN}^b(f)(\gamma) \in G_{\Sigma'}^0(\text{SEN}^b(f)(\Gamma)).$$

Next, for the structural rules:

- (Axiom) For $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, $\phi \vdash_\Sigma \phi \in \text{Seq}_\Sigma^0(\mathbf{F})$, whence, since, by (Axiom), $\phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$, $\phi \vdash_\Sigma \phi \in G_\Sigma^0(\emptyset)$.
- (Weakening) Let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\Phi \neq \emptyset$. Then, since $\Phi \cup \Psi \neq \emptyset$ and since, by (Weakening), $\Phi, \Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi)$, we conclude that $\Phi, \Psi \vdash_\Sigma \phi \in G_\Sigma^0(\Phi \vdash_\Sigma \phi)$.
- (Cut) Let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, with $\Phi \neq \emptyset$. Then $\Phi \cup \Psi \neq \emptyset$ and, since, by (Cut), $\Phi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \Psi, \Phi, \Psi \vdash_\Sigma \phi)$, we get $\Phi \vdash_\Sigma \phi \in G_\Sigma^0(\Phi \vdash_\Sigma \Psi, \Phi, \Psi \vdash_\Sigma \phi)$.
- (c) Suppose $\mathfrak{G}$ is of type 1 and $\mathcal{I}^\mathfrak{G}$ has no theorems. Clearly, $G^0 \leq G$ so that $C^{\mathfrak{G}^0} \leq C^\mathfrak{G}$. On the other hand, let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma^\mathfrak{G}(\Phi)$. Since $\mathcal{I}^\mathfrak{G}$ has no theorems, $\Gamma \neq \emptyset$. Moreover, by definition, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$. Thus, $\Phi \vdash_\Sigma \phi \in G_\Sigma^0(\emptyset)$. We conclude that $\phi \in C_\Sigma^{\mathfrak{G}^0}(\Phi)$. So $C^\mathfrak{G} \leq C^{\mathfrak{G}^0}$ and equality follows. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\Sigma \in |\mathbf{Sign}^b|$.

- A **Gentzen Σ -axiom** is a Σ -sequent $\gamma \in \text{Seq}_\Sigma(\mathbf{F})$;
- A **Gentzen Σ -rule** is a pair $\langle \Gamma, \gamma \rangle$, where $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$.

A **Gentzen axiom system** is a collection $\text{Ax} = \{\text{Ax}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^b|}$, where Ax_Σ is a set of Gentzen Σ -axioms, which is $\mathbf{Sign}^b$ -invariant.

A **Gentzen rule system** is a collection $\text{Ir} = \{\text{Ir}_\Sigma\}_{\Sigma \in |\mathbf{Sign}^b|}$, where Ir_Σ is a set of Gentzen Σ -rules, which is also $\mathbf{Sign}^b$ -invariant. Set

$$R = \text{Ax} \cup \text{Ir}.$$

The **Gentzen closure system** $G^R \subseteq \mathcal{P}(\text{Seq}(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}(\mathbf{F}))$ generated by R is the least closure system on $\text{Seq}(\mathbf{F})$, satisfying the structural rules, that contains R , i.e., such that, for all $\Sigma \in |\mathbf{Sign}^b|$,

- $\gamma \in G_\Sigma^R(\emptyset)$, for all $\gamma \in \text{Ax}_\Sigma$, and
- $\gamma \in G_\Sigma^R(\Gamma)$, for all $\langle \Gamma, \gamma \rangle \in \text{Ir}_\Sigma$.

We denote by $\mathfrak{G}^R = \langle \mathbf{F}, G^R \rangle$ the corresponding Gentzen π -institution, called the **Gentzen π -institution generated by R** .

A Finitary Parenthesis

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $R = \text{Ax} \cup \text{Ir}$ a set of finitary Gentzen axioms and rules of inference (i.e., such that the set of antecedents of all sequents involved is finite and the set of hypotheses of each rule of inference is also finite), and $\Gamma \subseteq \text{Seq}_\Sigma(\mathbf{F})$ a set of Σ -sequents. We define a family

$$\Xi_\Sigma^R(\Gamma) = \bigcup \{ \Xi_\Sigma^{R,n}(\Gamma) : n < \omega \},$$

where $\Xi_\Sigma^{R,n}(\Gamma)$ is defined by induction on $n < \omega$ as follows:

- $\Xi_\Sigma^{R,0}(\Gamma) = \{ \phi \vdash_\Sigma \phi : \phi \in \text{SEN}^b(\Sigma) \} \cup \text{Ax}_\Sigma \cup \Gamma$;
- For all $n \geq 0$, $\Phi \cup \Psi \cup \{ \phi \} \subseteq_f \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \Xi_\Sigma^{R,n+1}(\Gamma) = & \{ \Phi, \Psi \vdash_\Sigma \phi : \Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n}(\Gamma) \} \\ & \cup \{ \Phi \vdash_\Sigma \phi : \Phi \vdash_\Sigma \Psi, \Phi, \Psi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n}(\Gamma) \} \\ & \cup \{ \Phi \vdash_\Sigma \phi : \langle \Delta, \Phi \vdash_\Sigma \phi \rangle \in \text{Ir}_\Sigma, \Delta \subseteq \Xi_\Sigma^{R,n}(\Gamma) \}. \end{aligned}$$

We define $\Xi^R : \mathcal{P}(\text{Seq}(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}(\mathbf{F}))$, by letting $\Xi^R := \{ \Xi_\Sigma^R \}_{\Sigma \in |\mathbf{Sign}^b|}$, where $\Xi_\Sigma^R : \mathcal{P}(\text{Seq}_\Sigma(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}_\Sigma(\mathbf{F}))$ as defined above.

We show, next, that this is closure system on $\text{Seq}(\mathbf{F})$, which satisfies the structural rules, includes Ax and is closed under Ir .

Lemma 1518 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $R = \text{Ax} \cup \text{Ir}$ a collection of finitary axioms and rules of inference. $\Xi^R : \mathcal{P}(\text{Seq}(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}(\mathbf{F}))$ is a closure system on $\text{Seq}(\mathbf{F})$, satisfying the structural rules and including R .*

Proof: We show, first, that Ξ^R is a closure system on $\text{Seq}(\mathbf{F})$.

- Suppose $\Sigma \in |\mathbf{Sign}^b|$ and $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that $\gamma \in \Gamma$. Then $\gamma \in \Xi_{\Sigma}^{R,0}(\Gamma)$ and, hence, $\gamma \in \Xi_{\Sigma}^R(\Gamma)$.
- Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \Delta \cup \{\gamma\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that $\gamma \in \Xi_{\Sigma}^R(\Gamma)$ and $\Gamma \subseteq \Delta$. Then, for some $n < \omega$, $\gamma \in \Xi_{\Sigma}^{R,n}(\Gamma)$ and $\Gamma \subseteq \Delta$. We show by induction on n , that then $\gamma \in \Xi_{\Sigma}^{R,n}(\Delta)$.
 - If $n = 0$, then the conclusion follows directly from the inclusion $\Gamma \subseteq \Delta$.
 - Now suppose that $n > 0$ and that the conclusion holds for $n - 1$.
 - * If $\gamma = \Phi, \Psi \vdash_{\Sigma} \phi$, with $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Gamma)$, then, by the induction hypothesis, $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Delta)$, whence, it follows that $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n}(\Delta)$.
 - * If $\gamma = \Phi \vdash_{\Sigma} \phi$, with $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Gamma)$, we get, by the induction hypothesis, $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Delta)$, whence $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n}(\Delta)$.
 - * If $\gamma = \Phi \vdash_{\Sigma} \phi$, with $\langle \Upsilon, \Phi \vdash_{\Sigma} \phi \rangle \in \text{Ir}_{\Sigma}$ and $\Upsilon \subseteq \Xi_{\Sigma}^{R,n-1}(\Gamma)$, then, by the induction hypothesis, $\Upsilon \subseteq \Xi_{\Sigma}^{R,n-1}(\Delta)$, whence, again, $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n}(\Delta)$.
- Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that $\gamma \in \Xi_{\Sigma}^R(\Xi_{\Sigma}^R(\Gamma))$. Then, for some $n < \omega$, $\gamma \in \Xi_{\Sigma}^{R,n}(\Xi_{\Sigma}^R(\Gamma))$. We show by induction on n , that then $\gamma \in \Xi_{\Sigma}^R(\Gamma)$.
 - If $n = 0$, then γ is of the form $\phi \vdash_{\Sigma} \phi$ or is in Ax_{Σ} or in $\Xi_{\Sigma}^R(\Gamma)$. In the first two cases, it is in $\Xi_{\Sigma}^{R,0}(\Gamma) \subseteq \Xi_{\Sigma}^R(\Gamma)$ and in the last in $\Xi_{\Sigma}^R(\Gamma)$.
 - Suppose $n > 0$ and the conclusion holds for $n - 1$.
 - * If $\gamma = \Phi, \Psi \vdash_{\Sigma} \phi$, with $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Xi_{\Sigma}^R(\Gamma))$, then, by the induction hypothesis, $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^R(\Gamma)$, i.e., $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,m}(\Gamma)$, for some $m < \omega$. Thus $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,m+1}(\Gamma) \subseteq \Xi_{\Sigma}^R(\Gamma)$.
 - * If $\gamma = \Phi \vdash_{\Sigma} \phi$, with $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Xi_{\Sigma}^R(\Gamma))$, we get, by the induction hypothesis, $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^R(\Gamma)$. Since Ψ is finite, there exists $m > 0$, such that $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,m}(\Gamma)$. Thus, $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,m+1}(\Gamma) \subseteq \Xi_{\Sigma}^R(\Gamma)$.

- * If $\gamma = \Phi \vdash_{\Sigma} \phi$, with $\langle \Delta, \Phi \vdash_{\Sigma} \phi \rangle \in \text{Ir}_{\Sigma}$ and $\Delta \subseteq \Xi_{\Sigma}^{R,n-1}(\Xi_{\Sigma}^R(\Gamma))$, then, by the induction hypothesis, $\Delta \subseteq \Xi_{\Sigma}^R(\Gamma)$, whence, again, since Δ is finite, there exists $m > 0$, such that $\Delta \subseteq \Xi_{\Sigma}^{R,m}(\Gamma)$. Therefore, $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,m+1}(\Gamma) \subseteq \Xi_{\Sigma}^R(\Gamma)$.
- Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Gamma \cup \{\gamma\} \subseteq \text{Seq}_{\Sigma}(\mathbf{F})$, such that $\gamma \in \Xi_{\Sigma}^R(\Gamma)$, and let $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$. Then, for some $n < \omega$, $\gamma \in \Xi_{\Sigma}^{R,n}(\Gamma)$. We show by induction on n , that then $\text{SEN}^b(f)(\gamma) \in \Xi_{\Sigma'}^{R,n}(\text{SEN}^b(f)(\Gamma))$.
 - If $n = 0$, then γ is of the form $\phi \vdash_{\Sigma} \phi$ or in Ax_{Σ} or in Γ . In the first case, $\text{SEN}^b(f)(\gamma) = \text{SEN}^b(f)(\phi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in \Xi_{\Sigma'}^{R,0}(\text{SEN}^b(f)(\Gamma))$, by definition. In the second case, the conclusion holds by the postulated invariance of Ax under $\mathbf{Sign}^b$. In the last case, it holds because, by definition, $\text{SEN}^b(f)(\gamma) \in \Xi_{\Sigma'}^{R,0}(\text{SEN}^b(f)(\Gamma))$.
 - Suppose $n > 0$ and the conclusion holds for $n - 1$.
 - * If $\gamma = \Phi, \Psi \vdash_{\Sigma} \phi$, with $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Gamma)$, then, by the induction hypothesis,

$$\text{SEN}^b(f)(\Phi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in \Xi_{\Sigma'}^{R,n-1}(\text{SEN}^b(f)(\Gamma)),$$
 whence, by definition, $\text{SEN}^b(f)(\Phi \cup \Psi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in \Xi_{\Sigma'}^{R,n}(\text{SEN}^b(f)(\Gamma))$.
 - * If $\gamma = \Phi \vdash_{\Sigma} \phi$, with $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n-1}(\Gamma)$, we get, by the induction hypothesis, $\text{SEN}^b(f)(\Phi) \vdash_{\Sigma'} \text{SEN}^b(f)(\Psi)$, $\text{SEN}^b(f)(\Phi \cup \Psi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in \Xi_{\Sigma'}^{R,n-1}(\text{SEN}^b(f)(\Gamma))$. So, again by definition,

$$\text{SEN}^b(f)(\Phi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in \Xi_{\Sigma'}^{R,n}(\text{SEN}^b(f)(\Gamma)).$$
 - * If $\gamma = \Phi \vdash_{\Sigma} \phi$, with $\langle \Delta, \Phi \vdash_{\Sigma} \phi \rangle \in \text{Ir}_{\Sigma}$ and $\Delta \subseteq \Xi_{\Sigma}^{R,n-1}(\Gamma)$, then, by the induction hypothesis,

$$\text{SEN}^b(f)(\Delta) \subseteq \Xi_{\Sigma'}^{R,n}(\text{SEN}^b(f)(\Gamma)),$$
 whence, since Ir is invariant under $\mathbf{Sign}^b$, we get, by definition, $\text{SEN}^b(f)(\Phi) \vdash_{\Sigma'} \text{SEN}^b(f)(\phi) \in \Xi_{\Sigma'}^{R,n}(\text{SEN}^b(f)(\Gamma))$.

We have concluded the proof that Ξ^R is a closure system on $\text{Seq}(\mathbf{F})$.

Next, we show that it satisfies the structural rules.

- For (Axiom), if $\Sigma \in |\mathbf{Sign}^b|$, $\phi \in \text{SEN}^b(\Sigma)$, then, by definition, $\phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,0}(\emptyset) \subseteq \Xi_{\Sigma}^R(\emptyset)$.
- For (Weakening), if $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq_f \text{SEN}^b(\Sigma)$, such that $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^R(\Gamma)$, then, there exists $n < \omega$, such that $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n}(\Gamma)$. Therefore, by definition, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R,n+1}(\Gamma) \subseteq \Xi_{\Sigma}^R(\Gamma)$.

- For (Cut), if $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \Psi \cup \{\phi\} \subseteq_f \text{SEN}^b(\Sigma)$, such that $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi_\Sigma^R(\Gamma)$, then, since $\Psi \subseteq_f \text{SEN}^b(\Sigma)$, there exists $n < \omega$, such that $\Phi \vdash_\Sigma \Psi$, $\Phi, \Psi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n}(\Gamma)$. Thus, by definition, $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n+1}(\Gamma) \subseteq \Xi_\Sigma^R(\Gamma)$.

So Ξ^R does satisfy all three structural rules.

Finally, it does include all rules in R :

- For $\Sigma \in |\mathbf{Sign}^b|$, $\gamma \in \text{Ax}_\Sigma$, we have $\gamma \in \text{Ax}_\Sigma \subseteq \Xi_\Sigma^{R,0}(\emptyset) \subseteq \Xi_\Sigma^R(\emptyset)$.
- For $\Sigma \in |\mathbf{Sign}^b|$, $\langle \Gamma, \gamma \rangle \in \text{Ir}_\Sigma$, such that $\Gamma \subseteq \Xi_\Sigma^R(\Delta)$, since Γ is finite, there exists $n < \omega$, such that $\Gamma \subseteq \Xi_\Sigma^{R,n}(\Delta)$. Thus, by definition, $\gamma \in \Xi_\Sigma^{R,n+1}(\Delta) \subseteq \Xi_\Sigma^R(\Delta)$.

This concludes the proof of the statement. ■

We show that, given a system R of finitary Gentzen axioms and rules of inference, the closure $G_\Sigma^R(\Gamma)$ of a set Γ of Σ -sequents in the least Gentzen π -institution generated by R is exactly $\Xi_\Sigma^R(\Gamma)$.

Proposition 1519 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $R = \text{Ax} \cup \text{Ir}$ a set of finitary Gentzen axioms and rules of inference. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Gamma \subseteq \text{Seq}_\Sigma(\mathbf{F})$,*

$$G_\Sigma^R(\Gamma) = \Xi_\Sigma^R(\Gamma).$$

Proof: Suppose, first, that $\gamma \in \text{Seq}_\Sigma(\mathbf{F})$, such that $\gamma \in \Xi_\Sigma^R(\Gamma)$. Then, $\gamma \in \Xi_\Sigma^{R,n}(\Gamma)$, for some $n < \omega$. We show by induction on $n < \omega$ that, if $\gamma \in \Xi_\Sigma^{R,n}(\Gamma)$, then $\gamma \in G_\Sigma^R(\Gamma)$.

- The conclusion is obvious for $n = 0$, since, by definition, $G_\Sigma^R(\Gamma)$ satisfies the structural rules, contains Ax_Σ and, clearly, includes Γ ;
- A similar clause applies for the induction step:
 - If $\gamma = \Phi, \Psi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n-1}(\Gamma)$, then, by the induction hypothesis, $\Phi \vdash_\Sigma \phi \in G_\Sigma^R(\Gamma)$ and, since G^R satisfies the structural rules, $\Phi, \Psi \vdash_\Sigma \phi \in G_\Sigma^R(\Gamma)$ also.
 - If $\gamma = \Phi \vdash_\Sigma \phi$, with $\Phi \vdash_\Sigma \Psi \subseteq \Xi_\Sigma^{R,n-1}(\Gamma)$ and $\Psi \vdash_\Sigma \phi \in \Xi_\Sigma^{R,n-1}(\Gamma)$, then, again by the induction hypothesis, $\Phi \vdash_\Sigma \Psi \subseteq G_\Sigma^R(\Gamma)$ and $\Psi \vdash_\Sigma \phi \in G_\Sigma^R(\Gamma)$, whence, since G^R satisfies the structural rules, $\Phi \vdash_\Sigma \phi \in G_\Sigma^R(\Gamma)$.
 - If $\gamma = \Phi \vdash_\Sigma \phi$, with $\langle \Delta, \gamma \rangle \in \text{Ir}_\Sigma$ and $\Delta \subseteq \Xi_\Sigma^{R,n-1}(\Gamma)$, then, by the induction hypothesis, $\Delta \subseteq G_\Sigma^R(\Gamma)$ and, since G^R is closed under the rules of inference, we get that $\Phi \vdash_\Sigma \phi \in G_\Sigma^R(\Gamma)$.

We conclude that $\Xi_{\Sigma}^{R,n}(\Gamma) \subseteq G_{\Sigma}^R(\Gamma)$, for all $n < \omega$, and, therefore, $\Xi_{\Sigma}^R(\Gamma) \subseteq G_{\Sigma}^R(\Gamma)$.

Conversely, since, by Lemma 1518, $\Xi^R : \mathcal{P}(\text{Seq}(\mathbf{F})) \rightarrow \mathcal{P}(\text{Seq}(\mathbf{F}))$ is a closure system on $\text{Seq}(\mathbf{F})$, which satisfies the structural rules, contains Ax and is closed under Ir , we conclude by the minimality of G^R , that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Gamma \subseteq \text{Seq}_{\Sigma}(\mathbf{F})$, $G_{\Sigma}^R(\Gamma) \subseteq \Xi_{\Sigma}^R(\Gamma)$. From this, the conclusion follows. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$. Define a Gentzen π -institution $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$, as follows:

1. If $\mathcal{I}$ has theorems, $\mathfrak{G}^{\mathcal{I}}$ is of type 1 and if $\mathcal{I}$ does not have theorems, then $\mathfrak{G}^{\mathcal{I}}$ is of type 0;
2. Set $\text{Ax}^{\mathcal{I}} = \{\text{Ax}_{\Sigma}^{\mathcal{I}}\}_{\Sigma \in |\mathbf{Sign}^b|}$, where, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$\text{Ax}_{\Sigma}^{\mathcal{I}} = \{\Phi \vdash_{\Sigma} \phi : \phi \in C_{\Sigma}(\Phi)\}.$$

Let $R^{\mathcal{I}} := \text{Ax}^{\mathcal{I}}$. Then set $\mathfrak{G}^{\mathcal{I}} := \mathfrak{G}^{R^{\mathcal{I}}}$.

Of course, $\mathfrak{G}^{\mathcal{I}}$ is a Gentzen π -institution. Moreover, it turns out that, if $\mathcal{I}$ is finitary, then $\mathfrak{G}^{\mathcal{I}}$ is adequate for the π -institution $\mathcal{I}$.

Lemma 1520 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$. Then $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$ is a Gentzen π -institution adequate for $\mathcal{I}$.*

Proof: Note that, by hypothesis and Proposition 1519, $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, \Xi^{R^{\mathcal{I}}} \rangle$.

Let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq_f \text{SEN}^b(\Sigma)$. We must show that

$$\phi \in C_{\Sigma}(\Phi) \quad \text{iff} \quad \Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^{\mathcal{I}}}(\emptyset).$$

First, if $\phi \in C_{\Sigma}(\Phi)$, then, by definition $\Phi \vdash_{\Sigma} \phi \in \text{Ax}_{\Sigma}^{\mathcal{I}}$. Therefore, since $\text{Ax}_{\Sigma}^{\mathcal{I}} \subseteq \Xi_{\Sigma}^{R^{\mathcal{I}}}(\emptyset)$, we get $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^{\mathcal{I}}}(\emptyset)$.

Conversely, we must show that, if $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^{\mathcal{I}}}(\emptyset)$, then $\phi \in C_{\Sigma}(\Phi)$. We do this by showing, using induction on $n < \omega$, that

$$\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^{\mathcal{I}},n}(\emptyset) \quad \text{implies} \quad \phi \in C_{\Sigma}(\Phi).$$

- If $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^{\mathcal{I}},0}(\emptyset)$, then it is either of the form $\phi \vdash_{\Sigma} \phi$ or in $\text{Ax}_{\Sigma}^{\mathcal{I}}$. In the first case, the conclusion follows by the inflationarity of C and, in the second, by the definition of $\text{Ax}^{\mathcal{I}}$.
- Suppose $n > 0$ and that the conclusion holds for $n - 1$. Then, since $\text{Ir}^{\mathcal{I}} = \emptyset$, there are only two cases to consider.

- If $\Phi \vdash_{\Sigma} \phi$ is of the form $\Phi_1, \Phi_2 \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^x, n}(\emptyset)$, with $\Phi_1 \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^x, n-1}(\emptyset)$, then, by the induction hypothesis, $\phi \in C_{\Sigma}(\Phi_1)$ and, hence, by the monotonicity of C , $\phi \in C_{\Sigma}(\Phi_1, \Phi_2)$.
- If $\Phi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^x, n}(\emptyset)$, with $\Phi \vdash_{\Sigma} \Psi$, $\Phi, \Psi \vdash_{\Sigma} \phi \in \Xi_{\Sigma}^{R^x, n-1}(\emptyset)$, then, by the induction hypothesis, $\Psi \subseteq C_{\Sigma}(\Phi)$ and $\phi \in C_{\Sigma}(\Phi, \Psi)$, whence

$$\begin{aligned}
 \phi &\in C_{\Sigma}(\Phi, \Psi) \quad (\text{hypothesis}) \\
 &\subseteq C_{\Sigma}(\Phi, C_{\Sigma}(\Phi)) \quad (\text{monotonicity}) \\
 &\subseteq C_{\Sigma}(C_{\Sigma}(\Phi)) \quad (\text{monotonicity}) \\
 &= C_{\Sigma}(\Phi). \quad (\text{idempotency})
 \end{aligned}$$

This finishes the induction and concludes the proof. ■

End of the Finitary Parenthesis

20.2 $\mathfrak{G}$ -Structures and $\mathfrak{G}$ -Algebraic Systems

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathbb{L} = \langle \mathcal{A}, D \rangle$ an $\mathbf{F}$ -structure. $\mathbb{L}$ is a **$\mathfrak{G}$ -structure** or a **model of $\mathfrak{G}$** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\} \cup \{\Phi \vdash_{\Sigma} \phi\} \subseteq \text{Seq}_{\Sigma}(\mathbf{F})$,

$$\begin{aligned}
 &\Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\}) \text{ and } \alpha_{\Sigma}(\phi_i) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi_i)), \quad i \in I, \\
 &\quad \text{imply } \alpha_{\Sigma}(\phi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)).
 \end{aligned}$$

In relation to $\mathfrak{G}$ -structures, we use the following notation:

- $D \in \text{ClFam}^{\mathfrak{G}}(\mathcal{A})$ if $\langle \mathcal{A}, D \rangle$ is a $\mathfrak{G}$ -structure;
- $\text{Str}(\mathfrak{G})$ is the collection of all $\mathfrak{G}$ -structures;
- $\text{Str}^{\mathfrak{G}}(\mathcal{A})$ is the collection of all $\mathfrak{G}$ -structures on the $\mathbf{F}$ -algebraic system $\mathcal{A}$.

Let, again, $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ and $\mathbf{\Gamma} = \{\mathbf{\Gamma}_{\Sigma}\}_{\Sigma \in |\mathbf{Sign}^b|} \in \text{ThFam}(\mathfrak{G})$. Define $D^{\mathbf{\Gamma}} : \mathcal{P}\mathbf{SEN} \rightarrow \mathcal{P}\mathbf{SEN}$, by setting, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\Phi \subseteq \mathbf{SEN}^b(\Sigma)$,

$$D_{\Sigma}^{\mathbf{\Gamma}}(\Phi) = \{\phi \in \mathbf{SEN}^b(\Sigma) : \Phi \vdash_{\Sigma} \phi \in \mathbf{\Gamma}_{\Sigma}\}.$$

We show that $D^{\mathbf{\Gamma}}$, thus defined, is a closure family on $\mathbf{SEN}^b$ and, therefore, $\langle \mathcal{F}, D^{\mathbf{\Gamma}} \rangle$ is an $\mathbf{F}$ -structure. In fact, $\langle \mathcal{F}, D^{\mathbf{\Gamma}} \rangle$ is a $\mathfrak{G}$ -structure.

Lemma 1521 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ and $\mathbf{\Gamma} \in \text{ThFam}(\mathfrak{G})$. Then $\mathbb{L}^{\mathbf{\Gamma}} = \langle \mathcal{F}, C^{\mathbf{\Gamma}} \rangle$ is a $\mathfrak{G}$ -structure.*

Proof: We show, first, that D^Γ is a closure family on $\mathcal{F}$.

- Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in \Phi$. Then, by (Axiom) $\phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$. By (Weakening), $\Phi \vdash_\Sigma \phi \in G_\Sigma(\phi \vdash_\Sigma \phi)$. Therefore, by (Cut), $\Phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$. Therefore, $\Phi \vdash_\Sigma \phi \in \Gamma_\Sigma$ and, hence, $\phi \in D_\Sigma^\Gamma(\Phi)$.
- Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \Psi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in D_\Sigma^\Gamma(\Phi)$ and $\Phi \subseteq \Psi$. By definition, $\Phi \vdash_\Sigma \phi \in \Gamma_\Sigma$. Hence, by (Weakening) $\Psi \vdash_\Sigma \phi \in G_\Sigma(\Phi \vdash_\Sigma \phi) \subseteq G_\Sigma(\Gamma_\Sigma) = \Gamma_\Sigma$. We conclude that $\phi \in D_\Sigma^\Gamma(\Psi)$.
- Let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi))$. Then, by definition, $D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi)) \vdash_\Sigma \phi \in \Gamma_\Sigma$ and $D_\Sigma^\Gamma(\Phi) \vdash_\Sigma D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi)) \subseteq \Gamma_\Sigma$. Now we get

$$\begin{aligned}
 D_\Sigma^\Gamma(\Phi) \vdash_\Sigma \phi &\in G_\Sigma(D_\Sigma^\Gamma(\Phi), D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi)) \vdash_\Sigma \phi, \\
 &\quad D_\Sigma^\Gamma(\Phi) \vdash_\Sigma D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi))) \\
 &\subseteq G_\Sigma(D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi)) \vdash_\Sigma \phi, \\
 &\quad D_\Sigma^\Gamma(\Phi) \vdash_\Sigma D_\Sigma^\Gamma(D_\Sigma^\Gamma(\Phi))) \\
 &\subseteq G_\Sigma(\Gamma_\Sigma) \\
 &= \Gamma_\Sigma.
 \end{aligned}$$

Therefore, by definition, $\phi \in D_\Sigma^\Gamma(\Phi)$.

We conclude that $\mathbb{L}^\Gamma = \langle \mathcal{F}, D^\Gamma \rangle$ is an $\mathbf{F}$ -structure. We show, next, that $\mathbb{L}^\Gamma$ is a $\mathfrak{G}$ -structure. Let $\Sigma \in |\mathbf{Sign}^b|$, $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that

- $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ and
- $\phi_i \in D_\Sigma^\Gamma(\Phi_i)$, for all $i \in I$.

Then, by definition, $\Phi_i \vdash_\Sigma \phi_i \in \Gamma_\Sigma$, for all $i \in I$. Since $\Gamma \in \text{ThFam}(\mathfrak{G})$, we get $\Phi \vdash_\Sigma \phi \in \Gamma_\Sigma$. Thus, by definition, $\phi \in D_\Sigma^\Gamma(\Phi)$. So $\mathbb{L}^\Gamma = \langle \mathcal{F}, D^\Gamma \rangle$ is a $\mathfrak{G}$ -structure. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$, and $\mathbb{L} = \langle \mathcal{F}, D \rangle$ a $\mathfrak{G}$ -structure. We define $\Gamma^\mathbb{L} = \{\Gamma_\Sigma^\mathbb{L}\}_{\Sigma \in |\mathbf{Sign}^b|}$ by setting, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$\Gamma_\Sigma^\mathbb{L} = \{\Phi \vdash_\Sigma \phi \in \text{Seq}_\Sigma(\mathbf{F}) : \phi \in D_\Sigma(\Phi)\}.$$

We show that $\Gamma^\mathbb{L}$, thus defined, is a theory family of the Gentzen π -institution $\mathfrak{G}$.

Lemma 1522 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$, and $\mathbb{L} = \langle \mathcal{F}, D \rangle$ a $\mathfrak{G}$ -structure. Then $\Gamma^\mathbb{L} \in \text{ThFam}(\mathfrak{G})$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$, $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that

- $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ and
- $\Phi_i \vdash_\Sigma \phi_i \in \mathbf{\Gamma}_\Sigma^{\mathbb{L}}$, for all $i \in I$.

Then, by definition, $\phi_i \in D_\Sigma(\Phi_i)$, for all $i \in I$. Thus, since $\mathbb{L}$ is a $\mathfrak{G}$ -structure, $\phi \in D_\Sigma(\Phi)$. Therefore, $\Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma^{\mathbb{L}}$. We conclude $\mathbf{\Gamma}^{\mathbb{L}} \in \text{ThFam}(\mathfrak{G})$. ■

We show next that the two preceding constructions, of a $\mathfrak{G}$ -structure $\mathbb{L}^\Gamma$ out of a given theory family $\mathbf{\Gamma}$ of $\mathfrak{G}$ and of a theory family $\mathbf{\Gamma}^{\mathbb{L}}$ out of a given $\mathfrak{G}$ -structure $\mathbb{L} = \langle \mathcal{F}, D \rangle$ are inverses of one another.

Proposition 1523 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ and $\mathbb{L} = \langle \mathcal{F}, D \rangle$ an $\mathbf{F}$ -structure.*

- (a) $\mathbb{L} \in \text{Str}(\mathfrak{G})$ if and only if $\mathbf{\Gamma}^{\mathbb{L}} \in \text{ThFam}(\mathfrak{G})$ and $\mathbb{L} = \mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}}$;
- (b) $\mathbf{\Gamma} \in \text{ThFam}(\mathfrak{G})$ if and only if $\mathbb{L}^\Gamma \in \text{Str}(\mathfrak{G})$ and $\mathbf{\Gamma} = \mathbf{\Gamma}^{\mathbb{L}^\Gamma}$;
- (c) $\mathcal{I}^\mathfrak{G} = \langle \mathbf{F}, C^\mathfrak{G} \rangle$ is the smallest $\mathfrak{G}$ -structure on $\mathcal{F}$ and $C^\mathfrak{G} = D^{\text{Thm}(\mathfrak{G})}$.

Proof:

- (a) Suppose, first, that $\mathbb{L} = \langle \mathcal{F}, D \rangle \in \text{Str}(\mathfrak{G})$. Then, by Lemma 1522, $\mathbf{\Gamma}^{\mathbb{L}} \in \text{ThFam}(\mathfrak{G})$. Let $\Sigma \in |\mathbf{Sign}^b|$ and $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. We have

$$\begin{aligned} \phi \in D_\Sigma^{\mathbf{\Gamma}^{\mathbb{L}}}(\Phi) & \text{ iff } \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma^{\mathbb{L}} \\ & \text{ iff } \phi \in D_\Sigma(\Phi). \end{aligned}$$

So $D = D^{\mathbf{\Gamma}^{\mathbb{L}}}$.

Assume, conversely, that $\mathbf{\Gamma}^{\mathbb{L}} \in \text{ThFam}(\mathfrak{G})$ and $\mathbb{L} = \mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}}$. By Lemma 1521, $\mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}} \in \text{Str}(\mathfrak{G})$. Thus, $\mathbb{L} = \mathbb{L}^{\mathbf{\Gamma}^{\mathbb{L}}} \in \text{Str}(\mathfrak{G})$.

- (b) Suppose, first, that $\mathbf{\Gamma} \in \text{ThFam}(\mathfrak{G})$. Then, by Lemma 1521, $\mathbb{L}^\Gamma \in \text{Str}(\mathfrak{G})$. Let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma^{\mathbb{L}^\Gamma} & \text{ iff } \phi \in D_\Sigma^\Gamma(\Phi) \\ & \text{ iff } \Phi \vdash_\Sigma \phi \in \mathbf{\Gamma}_\Sigma. \end{aligned}$$

So $\mathbf{\Gamma} = \mathbf{\Gamma}^{\mathbb{L}^\Gamma}$.

Suppose, conversely, that $\mathbb{L}^\Gamma \in \text{Str}(\mathfrak{G})$ and $\mathbf{\Gamma} = \mathbf{\Gamma}^{\mathbb{L}^\Gamma}$. Then, by Lemma 1522, $\mathbf{\Gamma}^{\mathbb{L}^\Gamma} \in \text{ThFam}(\mathfrak{G})$ and, hence, $\mathbf{\Gamma} \in \text{ThFam}(\mathfrak{G})$.

(c) By Parts (a) and (b),

$$\begin{array}{ccc} \mathbb{L} & \xrightarrow{\quad} & \Gamma^{\mathbb{L}} \\ \mathbb{L}^{\Gamma} & \xleftarrow{\quad} & \Gamma \end{array}$$

are mutually inverse mappings between $\text{ThFam}(\mathfrak{G})$ and $\text{Str}^{\mathfrak{G}}(\mathcal{F})$ and both are clearly order-preserving. Thus $\mathbb{L}^{\text{Thm}(\mathfrak{G})} = \mathcal{I}^{\mathfrak{G}}$ is the least $\mathfrak{G}$ -structure on $\mathcal{F}$. ■

The next result shows that a Gentzen π -institution is complete with respect to class of all $\mathfrak{G}$ -structures.

Proposition 1524 (Completeness Theorem) *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. For all $\Sigma \in |\text{Sign}^b|$ and all $\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\} \cup \{\Phi \vdash_{\Sigma} \phi\} \subseteq \text{Seq}_{\Sigma}(\mathbf{F})$, $\Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\})$ if and only if, for every $\mathfrak{G}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$,*

$$\alpha_{\Sigma}(\phi_i) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi_i)), \quad i \in I, \quad \text{imply} \quad \alpha_{\Sigma}(\phi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)).$$

Proof: Let $\Sigma \in |\text{Sign}^b|$ and $\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\} \cup \{\Phi \vdash_{\Sigma} \phi\} \subseteq \text{Seq}_{\Sigma}(\mathbf{F})$.

Suppose, first, that $\Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\})$ and let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \text{Str}(\mathfrak{G})$, such that $\alpha_{\Sigma}(\phi_i) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi_i))$, for all $i \in I$. Then, by the definition of a $\mathfrak{G}$ -structure, $\alpha_{\Sigma}(\phi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi))$.

Assume, conversely, that the displayed condition in the statement holds. Let $\Gamma \in \text{ThFam}(\mathfrak{G})$, such that $\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\} \subseteq \Gamma_{\Sigma}$. Then, by definition, $\phi_i \in D_{\Sigma}^{\Gamma}(\Phi_i)$, for all $i \in I$. Since, by Lemma 1521, $\mathbb{L}^{\Gamma}$ is a $\mathfrak{G}$ -structure, we get, by hypothesis, $\phi \in D_{\Sigma}^{\Gamma}(\Phi)$. Therefore, $\Phi \vdash_{\Sigma} \phi \in \Gamma_{\Sigma}$. We conclude that $\Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\{\Phi_i \vdash_{\Sigma} \phi_i : i \in I\})$. ■

Next, we show that the property of being a model of a Gentzen π -institution is preserved under biological morphisms.

Proposition 1525 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ two $\mathbf{F}$ -algebraic systems, $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ two $\mathbf{F}$ -structures and $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism. $\mathbb{L}$ is a $\mathfrak{G}$ -structure if and only if $\mathbb{L}'$ is a $\mathfrak{G}$ -structure.*

Proof: For the proof, it suffices to notice that, since $\langle H, \gamma \rangle$ is a biological morphism, for all $\Sigma \in |\text{Sign}^b|$ and all $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$,

$$\begin{aligned} \alpha_{\Sigma}(\phi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)) & \quad \text{iff} \quad \gamma_{F(\Sigma)}(\alpha_{\Sigma}(\phi)) \in D'_{H(F(\Sigma))}(\gamma_{F(\Sigma)}(\alpha_{\Sigma}(\Phi))) \\ & \quad \text{iff} \quad \alpha'_{\Sigma}(\phi) \in D'_{F'(\Sigma)}(\alpha'_{\Sigma}(\Phi)). \end{aligned}$$

The rest of the argument is straightforward: If $\mathbb{L}$ is a $\mathfrak{G}$ -structure, then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash \phi_i : i \in I\})$ and $\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, for all $i \in I$, we get $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))$, for all $i \in I$, whence, by hypothesis, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$, which gives $\alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi))$. We conclude that $\mathbb{L}'$ is also a $\mathfrak{G}$ -structure. If, conversely, $\mathbb{L}'$ is a $\mathfrak{G}$ -structure, then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$, such that $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash \phi_i : i \in I\})$ and $\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i))$, for all $i \in I$, we get $\alpha'_\Sigma(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi_i))$, for all $i \in I$, whence, by hypothesis, $\alpha'_\Sigma(\phi) \in D'_{F'(\Sigma)}(\alpha'_\Sigma(\Phi))$, which gives $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. We conclude that $\mathbb{L}$ is also a $\mathfrak{G}$ -structure. $\blacksquare$

In particular, we obtain

Corollary 1526 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. An $\mathbf{F}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$ is a $\mathfrak{G}$ -structure if and only if its reduction $\mathbb{L}^*$ is a $\mathfrak{G}$ -structure.*

Proof: This follows directly from Proposition 1525, since the quotient morphism $\langle I, \pi \rangle : \mathbb{L} \vdash \mathbb{L}^*$ is a biological morphism. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. $\mathcal{A}$ is a **$\mathfrak{G}$ -algebraic system** if it is the underlying algebraic system of a reduced $\mathfrak{G}$ -structure. We denote the class of all $\mathfrak{G}$ -algebraic systems by $\text{AlgSys}(\mathfrak{G})$, i.e., we have

$$\text{AlgSys}(\mathfrak{G}) = \{ \mathcal{A} : (\exists D \in \text{ClFam}^{\mathfrak{G}}(\mathcal{A}))(\tilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}) \}.$$

We show that, if a Gentzen π -institution $\mathfrak{G}$ happens to be adequate for a π -institution $\mathcal{I}$, then every $\mathfrak{G}$ -algebraic system is also an $\mathcal{I}$ -algebraic system.

Lemma 1527 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ that is adequate for $\mathcal{I}$. Then:*

- (a) *Every $\mathfrak{G}$ -structure is an $\mathcal{I}$ -structure;*
- (b) $\text{AlgSys}(\mathfrak{G}) \subseteq \text{AlgSys}(\mathcal{I})$.

Proof:

- (a) Let $\mathbb{L} = \langle \mathcal{A}, D \rangle \in \text{Str}(\mathfrak{G})$. Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \in C_\Sigma(\Phi)$. By the adequacy of $\mathfrak{G}$ for $\mathcal{I}$, $\Phi \vdash_\Sigma \phi \in G_\Sigma(\emptyset)$. Since $\mathbb{L} \in \text{Str}(\mathfrak{G})$, $\alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$. Thus, by Lemma 50, $\mathbb{L}$ is an $\mathcal{I}$ -structure.

- (b) Assume that $\mathfrak{G}$ is adequate for $\mathcal{I}$ and let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \text{AlgSys}(\mathfrak{G})$. Then, there exists a $\mathfrak{G}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, such that $\tilde{\Omega}^{\mathcal{A}}(D) = \Delta^{\mathcal{A}}$. To conclude that $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$, it suffices, by Proposition 1436, to show that $\mathbb{L} \in \text{Str}^{\mathcal{I}}(\mathcal{A})$. But this was done in Part (a). ■

20.3 Fully Adequate Gentzen π -Institutions

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$, such that $\mathfrak{G}$ is adequate for $\mathcal{I}$. Then, with $\mathcal{I}$ may be associated two classes of $\mathbf{F}$ -algebraic systems and two classes of $\mathcal{I}$ -structures:

- $\mathcal{I}$ -algebraic systems and full $\mathcal{I}$ -structures;
- $\mathfrak{G}$ -algebraic systems and $\mathfrak{G}$ -structures.

We devise certain conditions that, when possible to enforce, would guarantee that a Gentzen π -institution $\mathfrak{G}$ adequate for $\mathcal{I}$ can be picked in such a way as to have $\text{AlgSys}(\mathfrak{G}) = \text{AlgSys}(\mathcal{I})$ and $\text{Str}(\mathfrak{G}) = \text{FStr}(\mathcal{I})$.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. $\mathfrak{G}$ is said to be **fully adequate for $\mathcal{I}$** if one of the following two conditions holds:

- $\mathcal{I}$ has theorems, $\mathfrak{G}$ is of type 1 and, for every $\mathbf{F}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \text{FStr}(\mathcal{I})$ if and only if $\mathbb{L} \in \text{Str}(\mathfrak{G})$;
- $\mathcal{I}$ does not have theorems, $\mathfrak{G}$ is of type 0 and, for every $\mathbf{F}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \text{FStr}(\mathcal{I})$ if and only if $\mathbb{L} \in \text{Str}(\mathfrak{G})$ and $\mathbb{L}$ does not have theorems.

We show that, if $\mathfrak{G}$ is fully adequate for $\mathcal{I}$, then it is also adequate for $\mathcal{I}$.

Proposition 1528 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. If $\mathfrak{G}$ is fully adequate for $\mathcal{I}$, then $\mathfrak{G}$ is adequate for $\mathcal{I}$.*

Proof: Assume that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$ and let $\Sigma \in |\mathbf{Sign}^b|$, $\Phi \cup \{\phi\} \subseteq \text{SEN}^b(\Sigma)$.

If $\phi \in C_{\Sigma}^{\mathfrak{G}}(\Phi)$, then, by definition, $\Phi \vdash_{\Sigma} \phi \in G_{\Sigma}(\emptyset)$. Since, by Corollary 1428, $\langle \mathcal{F}, C \rangle \in \text{FStr}(\mathcal{I})$, we get, by hypothesis, $\langle \mathcal{F}, C \rangle \in \text{Str}(\mathfrak{G})$. Therefore, $\phi \in C_{\Sigma}(\Phi)$.

Assume, conversely, that $\phi \in C_{\Sigma}(\Phi)$. Since, by Proposition 1523, $\langle \mathcal{F}, C^{\mathfrak{G}} \rangle \in \text{Str}(\mathfrak{G})$, which, additionally, does not have theorems, if $\mathcal{I}$ has no theorems, we get, by hypothesis, $\langle \mathcal{F}, C^{\mathfrak{G}} \rangle \in \text{FStr}(\mathcal{I})$. But, by Corollary 1428, $\langle \mathcal{F}, C \rangle$ is

the weakest full $\mathcal{I}$ -structure on $\mathcal{F}$. Therefore, since $\phi \in C_\Sigma(\Phi)$, we get that $\phi \in C_\Sigma^\mathfrak{G}(\Phi)$. $\blacksquare$

We provide next a characterization of full adequacy, which also showcases its features and hints at why it is a useful notion in trying to connect π -institutions with Gentzen π -institutions.

Proposition 1529 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. $\mathfrak{G}$ is fully adequate for $\mathcal{I}$ if and only if*

1. $\text{AlgSys}(\mathfrak{G}) = \text{AlgSys}(\mathcal{I})$;
2. For all $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$, $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ is the only reduced $\mathfrak{G}$ -structure on $\mathcal{A}$ (without theorems if $\mathcal{I}$ does not have any);
3. $\mathcal{I}$ has theorems and $\mathfrak{G}$ is of type 1 or $\mathcal{I}$ does not have theorems and $\mathfrak{G}$ is of type 0.

Proof: Assume $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. Note that Condition 3 holds by definition. By Proposition 1528, $\mathcal{I}$ is adequate for $\mathcal{I}$. By Lemma 1527, $\text{AlgSys}(\mathfrak{G}) \subseteq \text{AlgSys}(\mathcal{I})$. If, on the other hand, $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$, then $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$ -structure. Thus, by hypothesis, it is a reduced $\mathfrak{G}$ -structure. It follows that $\mathcal{A} \in \text{AlgSys}(\mathfrak{G})$. This shows that Condition 1 also holds. It remains now to prove Condition 2. To this end, suppose $\mathcal{A} \in \text{AlgSys}(\mathcal{I})$. Then $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ is a reduced full $\mathcal{I}$ -structure. By hypothesis, $\langle \mathcal{A}, \text{FiFam}^\mathcal{I}(\mathcal{A}) \rangle$ is a reduced $\mathfrak{G}$ -structure. By the Isomorphism Theorem 1445, it is the only full $\mathcal{I}$ -structure on $\mathcal{A}$ that is reduced. Hence, by hypothesis, it is the only reduced $\mathfrak{G}$ -structure on $\mathcal{A}$. This proves Condition 2 and concludes the “only if”.

Assume, conversely, that Conditions 1-3 hold. Then, for all $\mathbf{F}$ -structures $\mathbb{L} = \langle \mathcal{A}, D \rangle$,

$$\begin{aligned} \mathbb{L} \in \text{FStr}(\mathcal{I}) & \text{ iff } \mathcal{A}^* \in \text{AlgSys}(\mathcal{I}) \text{ and } \mathcal{D}^* = \text{FiFam}^\mathcal{I}(\mathcal{A}^*) \\ & \text{ iff } \mathcal{A}^* \in \text{AlgSys}(\mathfrak{G}) \text{ and } \langle \mathcal{A}^*, \mathcal{D}^* \rangle \in \text{Str}(\mathfrak{G}) \\ & \quad (\text{w/o theorems if } \mathcal{I} \text{ does not have any}) \\ & \text{ iff } \langle \mathcal{A}, \mathcal{D} \rangle \in \text{Str}(\mathfrak{G}) \\ & \quad (\text{w/o theorems if } \mathcal{I} \text{ does not have any}). \end{aligned}$$

This, combined with Condition 3, gives that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. $\blacksquare$

If a π -institution $\mathcal{I}$ has a fully adequate Gentzen π -institution, then that Gentzen π -institution is unique.

Proposition 1530 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$, $\mathfrak{G}' = \langle \mathbf{F}, G' \rangle$ two Gentzen π -institutions based on $\mathbf{F}$. If $\mathfrak{G}$ and $\mathfrak{G}'$ are fully adequate for $\mathcal{I}$, then $\mathfrak{G} = \mathfrak{G}'$.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$, $\{\Phi_i \vdash_\Sigma \phi_i : i \in I\} \cup \{\Phi \vdash_\Sigma \phi\} \subseteq \text{Seq}_\Sigma(\mathbf{F})$. Then, we get $\Phi \vdash_\Sigma \phi \in G_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$ if and only if, by Proposition 1524, for every $\langle \mathcal{A}, D \rangle \in \text{Str}(\mathfrak{G})$,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)), \quad i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$$

if and only if, by full adequacy, for all $\langle \mathcal{A}, D \rangle \in \text{FStr}(\mathcal{I})$,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)), \quad i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$$

if and only if, by full adequacy, for every $\langle \mathcal{A}, D \rangle \in \text{Str}(\mathfrak{G}')$,

$$\alpha_\Sigma(\phi_i) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi_i)), \quad i \in I, \quad \text{imply} \quad \alpha_\Sigma(\phi) \in D_{F(\Sigma)}(\alpha_\Sigma(\Phi))$$

if and only if, by Proposition 1524, $\Phi \vdash_\Sigma \phi \in G'_\Sigma(\{\Phi_i \vdash_\Sigma \phi_i : i \in I\})$. Therefore, $G = G'$ and, hence, $\mathfrak{G} = \mathfrak{G}'$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system. Recall the notation for the family of $\mathbf{F}$ -equations $\text{Eq}(\mathbf{F}) = \{\text{Eq}_\Sigma(\mathbf{F})\}_{\Sigma \in |\mathbf{Sign}^b|}$, where $\text{Eq}_\Sigma(\mathbf{F}) = \text{SEN}^b(\Sigma)^2$. Let $\mathbf{K}$ be a class of $\mathbf{F}$ -algebraic systems and recall the relative equational consequence of $\mathbf{K}$

$$C^K = \{C_\Sigma^K\}_{\Sigma \in |\mathbf{Sign}^b|} : \mathcal{P}(\text{Eq}(\mathbf{F})) \rightarrow \mathcal{P}(\text{Eq}(\mathbf{F}))$$

given, for all $\Sigma \in |\mathbf{Sign}^b|$, $E \cup \{\phi \approx \psi\} \subseteq \text{Eq}_\Sigma(\mathbf{F})$, by

$$\begin{aligned} \phi \approx \psi \in C_\Sigma^K(E) \quad \text{iff} \quad & \text{for all } \mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle \in \mathbf{K}, \\ & E \subseteq \text{Ker}_\Sigma(\mathcal{A}) \text{ implies } \langle \phi, \psi \rangle \in \text{Ker}_\Sigma(\mathcal{A}). \end{aligned}$$

We show that the structure $\mathcal{Q}^K = \langle \mathbf{F}^2, C^K \rangle$ is a π -structure.

Lemma 1531 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and let $\mathbf{K}$ be a class of $\mathbf{F}$ -algebraic systems. Then $\mathcal{Q}^K = \langle \mathbf{F}^2, C^K \rangle$ is a π -structure.*

Proof: By Lemma ???. ■

Recall from Proposition 115, that $\mathcal{Q}^K$ satisfies the properties of reflexivity, symmetry, transitivity, congruence and invariance. So we have

Corollary 1532 *et $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and let $\mathbf{K}$ be a class of $\mathbf{F}$ -algebraic systems. Then $\mathcal{Q}^K = \langle \mathbf{F}^2, C^K \rangle$ is an equational π -structure.*

Proof: By Lemma 1531 and Proposition 115. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ and $\mathbf{K}$ a class of $\mathbf{F}$ -algebraic systems. According to

the framework developed in Chapter 12, we say that $\mathfrak{G}$ is **equivalent to** $\mathcal{Q}^K$ if there exists a conjugate pair of translations $(t, s) : \mathfrak{G} \rightleftarrows \mathcal{Q}^K$, where

$$\begin{array}{ccc} t : & \mathfrak{G} & \longrightarrow \mathcal{Q}^K \\ & \mathfrak{G} & \longleftarrow \mathcal{Q}^K : s \end{array}$$

We will focus specifically on the case in which the translation $sq : \text{Eq}(\mathbf{F}) \rightarrow \text{SenFam}(\mathfrak{G})$ is natural and given by the natural transformation $\kappa : \text{Eq}(\mathbf{F}) \rightarrow \mathcal{P}(\text{Seq}(\mathbf{F}))$, determined, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$, by

$$\kappa_\Sigma(\phi, \psi) = \{\phi \vdash_\Sigma \psi, \psi \vdash_\Sigma \phi\}.$$

Recall that, in this case, since κ does not have any parameters, we have that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \text{SEN}^b(\Sigma)$,

$$sq_\Sigma[\phi \approx \psi] = \{sq_{\Sigma, \Sigma'}[\phi \approx \psi]\}_{\Sigma' \in |\mathbf{Sign}^b|},$$

where

$$sq_{\Sigma, \Sigma'}[\phi \approx \psi] = \{\text{SEN}^b(f)(\phi \vdash_\Sigma \psi), \text{SEN}^b(\psi \vdash_\Sigma \phi) : f \in \mathbf{Sign}^b(\Sigma, \Sigma')\}.$$

Finally, we say that the Gentzen π -institution $\mathfrak{G}$ **has** or **satisfies Congruence** if, for all σ^b in N^b , all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_i, \psi_i \in \text{SEN}^b(\Sigma)$, $i < k$,

$$\sigma_\Sigma^b(\vec{\phi}) \vdash_\Sigma \sigma_\Sigma^b(\vec{\psi}) \in G_\Sigma(\bigcup_{i < k} sq_\Sigma[\phi_i \approx \psi_i]).$$

We show that the equivalence of a Gentzen π -institution $\mathfrak{G}$ with an equational π -institution $\mathcal{Q}^K$ implies that $\mathfrak{G}$ satisfies Congruence and, moreover, that it has interesting consequences for any π -institution for which $\mathfrak{G}$ happens to be adequate. More precisely, such a π -institution must be self extensional and the variety generated by its Lindenbaum-Tarski $\mathbf{F}$ -algebraic system must coincide with the variety generated by the class $\mathbf{K}$.

Proposition 1533 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$ and $\mathbf{K}$ a class of $\mathbf{F}$ -algebraic systems. If $\mathfrak{G}$ is equivalent to $\mathcal{Q}^K$ via a conjugate pair $(t, sq) : \mathfrak{G} \rightleftarrows \mathcal{Q}^K$, then $\mathfrak{G}$ satisfies Congruence. If, in addition, $\mathfrak{G}$ is adequate for a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, then $\mathcal{I}$ is self extensional and $\mathbf{Q}(\mathbf{K}) = \mathbf{K}^\mathcal{I}$.*

Proof: Suppose $\mathfrak{G}$ is equivalent to $\mathcal{Q}^K$ via a conjugate pair $(t, sq) : \mathfrak{G} \rightleftarrows \mathcal{Q}^K$ and let $\sigma^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , $\Sigma \in |\mathbf{Sign}^b|$ and $\phi_i, \psi_i \in \text{SEN}^b(\Sigma)$, $i < k$. By Proposition 115,

$$\sigma_\Sigma^b(\vec{\phi}) \approx \sigma_\Sigma^b(\vec{\psi}) \in C_\Sigma^K(\{\phi_i \approx \psi_i : i < k\}).$$

Thus, by the hypothesis,

$$\sigma_\Sigma^b(\vec{\phi}) \vdash_\Sigma \sigma_\Sigma^b(\vec{\psi}) \in G_\Sigma(\bigcup_{i < k} sq_\Sigma[\phi_i \approx \psi_i]).$$

Thus, $\mathfrak{G}$ satisfies Congruence.

Suppose, next, that $\mathcal{I} = \langle \mathbf{F}, C \rangle$ is a π -institution, for which $\mathfrak{G}$ is adequate, and let $\sigma^b : (\text{SEN}^b)^k \rightarrow \text{SEN}^b$ in N^b , $\Sigma \in |\mathbf{Sign}^b|$ and $\phi_i, \psi_i \in \text{SEN}^b(\Sigma)$, $i < k$, such that $C_\Sigma(\phi_i) = C_\Sigma(\psi_i)$. By structurality, for all $\Sigma' \in |\mathbf{Sign}^b|$ and all $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, $C_{\Sigma'}(\text{SEN}^b(f)(\phi)) = C_{\Sigma'}(\text{SEN}^b(f)(\psi))$. Then, by adequacy,

$$\text{SEN}^b(f)(\phi_i \vdash_\Sigma \psi_i), \text{SEN}^b(f)(\psi_i \vdash_\Sigma \phi_i) \in G_{\Sigma'}(\emptyset).$$

Since $\mathfrak{G}$ has Congruence, we get

$$\begin{aligned} \sigma_\Sigma^b(\vec{\phi}) \vdash_\Sigma \sigma_\Sigma^b(\vec{\psi}), \sigma_\Sigma^b(\vec{\psi}) \vdash_\Sigma \sigma_\Sigma^b(\vec{\phi}) &\in G_\Sigma(\bigcup_{i < k} sq_\Sigma[\phi_i \approx \psi_i]) \\ &\subseteq G_\Sigma(G_\Sigma(\emptyset)) \\ &= G_\Sigma(\emptyset) \end{aligned}.$$

Again using adequacy, $C_\Sigma(\sigma_\Sigma^b(\vec{\phi})) = C_\Sigma(\sigma_\Sigma^b(\vec{\psi}))$. Therefore, $\tilde{\lambda}(\mathcal{I})$ is a congruence system on $\mathbf{F}$ and, by Proposition 1464, $\mathcal{I}$ is self extensional.

For the last claim, recall that

$$\begin{aligned} \mathbf{Q}(\mathbf{K}) &= \{\mathcal{A} : \text{Ker}(\mathbf{K}) \leq \text{Ker}(\mathcal{A})\}; \\ \mathbf{K}^\mathcal{I} = \mathbf{Q}(\mathcal{F}/\tilde{\Omega}(\mathcal{I})) &= \{\mathcal{A} : \tilde{\Omega}(\mathcal{I}) \leq \text{Ker}(\mathcal{A})\}. \end{aligned}$$

Moreover, note that $\text{Ker}(\mathbf{K}) = \text{Thm}(\mathcal{Q}^\mathbf{K})$. Therefore, to see that the claim holds, it suffices to show that $\text{Thm}(\mathcal{Q}^\mathbf{K}) = \tilde{\Omega}(\mathcal{I})$. To this end, let $\Sigma \in |\mathbf{Sign}^b|$, $\phi, \psi \in \text{SEN}^b(\Sigma)$. Then we have

$$\begin{aligned} \phi \approx \psi \in D_\Sigma^\mathbf{K}(\emptyset) &\text{ iff } sq_\Sigma[\phi \approx \psi] \leq G(\emptyset) \quad (\text{by hypothesis}) \\ &\text{ iff } C_\Sigma(\phi) = C_\Sigma(\psi) \quad (\text{by adequacy}) \\ &\text{ iff } \langle \phi, \psi \rangle \in \tilde{\lambda}_\Sigma(\mathcal{I}) \quad (\text{by definition}) \\ &\text{ iff } \langle \phi, \psi \rangle \in \tilde{\Omega}_\Sigma(\mathcal{I}). \quad (\text{by self extensionality}) \end{aligned}$$

Thus, we have $\mathbf{Q}(\mathbf{K}) = \mathbf{K}^\mathcal{I}$, as claimed. $\blacksquare$

In closing the section, we show that, given a π -institution $\mathcal{I}$ that has an adequate finitary Gentzen π -institution $\mathfrak{G}$, satisfying Congruence, the equational consequence based on the variety $\mathbf{K}^\mathcal{I}$ is translated into the consequence of the Gentzen π -institution via sq .

Proposition 1534 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a finitary Gentzen π -institution, having Congruence, that is adequate for $\mathcal{I}$. Then, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $E \cup \{\phi, \psi\} \subseteq \text{SEN}^b(\Sigma)$,*

$$\phi \approx \psi \in D_\Sigma^{\mathbf{K}^\mathcal{I}}(E) \quad \text{implies} \quad sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E]).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$, $E \cup \{\phi, \psi\} \subseteq \text{SEN}^b(\Sigma)$, such that $\phi \approx \psi \in D_\Sigma^{\mathbf{K}^\mathcal{I}}(E)$. By Theorem 119, we have $D^{\mathbf{K}^\mathcal{I}} = \Xi^{\text{Ker}(\mathbf{K}^\mathcal{I})} = \Xi^{\tilde{\Omega}(\mathcal{I})}$. So, we get $\phi \approx \psi \in \Xi_\Sigma^{\tilde{\Omega}(\mathcal{I})}(E)$. We show by induction on $n < \omega$, that, for all $n < \omega$,

$$\phi \approx \psi \in \Xi_\Sigma^{\tilde{\Omega}(\mathcal{I}), n}(E) \quad \text{implies} \quad sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E]).$$

- For $n = 0$, we must have $\phi = \psi$ or $\langle \phi, \psi \rangle \in \tilde{\Omega}_\Sigma(\mathcal{I})$ or $\phi \approx \psi \in E$.

In the first case the conclusion follows by (Axiom).

In the second case, we have that $C_\Sigma(\phi) = C_\Sigma(\psi)$, whence, by adequacy, $sq_\Sigma[\phi \approx \psi] \leq G(\emptyset) \leq G(sq_\Sigma[E])$.

In the last case, the conclusion follows by the inflationarity of G .

- Suppose, now, that the implication holds for $n > 0$ and let $\Sigma \in |\mathbf{Sign}^b|$, $E \cup \{\phi \approx \psi\} \subseteq \text{Eq}_\Sigma(\mathbf{F})$, such that $\phi \approx \psi \in \Xi_\Sigma^{\tilde{\Omega}(\mathcal{I}), n+1}(E)$.

If $\psi \approx \phi \in \Xi_\Sigma^{\tilde{\Omega}(\mathcal{I}), n}(E)$, then, by the induction hypothesis, $sq_\Sigma[\psi \approx \phi] \leq G(sq_\Sigma[E])$. Since $sq_\Sigma[\phi \approx \psi] = sq_\Sigma[\psi \approx \phi]$, we conclude that $sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E])$.

If $\phi \approx \chi, \chi \approx \psi \in \Xi_\Sigma^{\tilde{\Omega}(\mathcal{I}), n}(E)$, then, by the induction hypothesis,

$$sq_\Sigma[\phi \approx \chi], sq_\Sigma[\chi \approx \psi] \leq G(sq_\Sigma[E]).$$

Using (Cut) and monotonicity, we get

$$\begin{aligned} sq_\Sigma[\phi \approx \psi] &\leq G(sq_\Sigma[\phi \approx \chi], sq_\Sigma[\chi \approx \psi]) \\ &\leq G(sq_\Sigma[E]). \end{aligned}$$

If $\phi \approx \psi$ is of the form $\sigma_\Sigma^b(\vec{\phi}) \approx \sigma_\Sigma^b(\vec{\psi})$, with $\phi_i \approx \psi_i \in \Xi_\Sigma^{\tilde{\Omega}(\mathcal{I}), n}(E)$, $i < k$, then, by the induction hypothesis, $sq_\Sigma[\phi_i \approx \psi_i] \leq G(sq_\Sigma[E])$ $i < k$. Then, since $\mathfrak{G}$ has Congruence, we conclude

$$\begin{aligned} sq_\Sigma[\sigma_\Sigma^b(\vec{\phi}) \approx \sigma_\Sigma^b(\vec{\psi})] &\leq G(\bigcup_{i < k} sq_\Sigma[\phi_i \approx \psi_i]) \\ &\leq G(sq_\Sigma[E]). \end{aligned}$$

Last, assume that $\phi \approx \psi$ has the form $\text{SEN}^b(f)(\phi' \approx \psi')$, for some $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma', \Sigma)$, such that $\phi' \approx \psi' \in \Xi_{\Sigma'}^{\tilde{\Omega}(\mathcal{I}), n}(E)$. Then, by the induction hypothesis, $sq_{\Sigma'}[\phi' \approx \psi'] \leq G(sq_{\Sigma'}[E])$. But, note that $sq_\Sigma[\phi \approx \psi] = sq_\Sigma[\text{SEN}^b(f)(\phi' \approx \psi')] \leq sq_{\Sigma'}[\phi' \approx \psi']$. Thus, we get $sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E])$.

We conclude that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $E \cup \{\phi \approx \psi\} \subseteq \text{Eq}_\Sigma(\mathbf{F})$, $\phi \approx \psi \in D_\Sigma^{\mathbf{K}^\mathcal{I}}(E)$ implies that $sq_\Sigma[\phi \approx \psi] \leq G(sq_\Sigma[E])$. $\blacksquare$

20.4 Smoothness and Finitary Adaptations

In this section we define smooth Gentzen π -institutions and we also adapt some of the preceding results to the case of finitary π -institutions. This work is meant to pave the way for upcoming results on self extensionality and

conjunction, presented in the next section, and on self extensionality and the deduction detachment theorem, which follow in the section after that.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. We say that $\mathfrak{G}$ is **smooth** if G operates on finite sequents and it is systemic, i.e., by Proposition 149, for all $\Sigma, \Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$, $\Phi \cup \{\phi\} \subseteq \mathbf{SEN}^b(\Sigma)$,

$$\mathbf{SEN}^b(f)(\Phi \vdash_{\Sigma} \phi) \in G_{\Sigma'}(\Phi \vdash_{\Sigma} \phi).$$

In the case of smooth Gentzen systems, the equivalence of the Gentzen system with an algebraic π -structure may be simplified as follows.

Proposition 1535 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a smooth Gentzen π -institution and $\mathbf{K}$ a class of $\mathbf{F}$ -algebraic systems. Then $\mathfrak{G}$ is equivalent to $\mathcal{Q}^{\mathbf{K}}$ via the conjugate pair $(t, sq) : \mathfrak{G} \rightleftarrows \mathcal{Q}^{\mathbf{K}}$ if and only if its is equivalent to $\mathcal{Q}^{\mathbf{K}}$ via the conjugate pair $(t, \kappa) : \mathfrak{G} \rightleftarrows \mathcal{Q}^{\mathbf{K}}$.*

Proof: By Lemma 892, it is enough to show that, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$G(sq_{\Sigma}[\phi \approx \psi]) = G(\kappa_{\Sigma}(\phi \approx \psi)).$$

This is, however, a consequence of smoothness. ■

Moreover, for a smooth Gentzen π -institution $\mathfrak{G}$, satisfying Congruence is equivalent to an apparently simpler condition.

Proposition 1536 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a smooth Gentzen π -institution. $\mathfrak{G}$ satisfies Congruence if and only if, for all σ^b in N^b , all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_i, \psi_i \in \mathbf{SEN}^b(\Sigma)$, $i < k$,*

$$\sigma_{\Sigma}^b(\vec{\phi}) \vdash_{\Sigma} \sigma_{\Sigma}^b(\vec{\psi}) \in G_{\Sigma}(\{\phi_i \vdash_{\Sigma} \psi_i, \psi_i \vdash_{\Sigma} \phi_i : i < k\}).$$

Proof: Assume, first, that $\mathfrak{G}$ satisfies Congruence. Then, for all σ^b in N^b , all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_i, \psi_i \in \mathbf{SEN}^b(\Sigma)$, $i < k$,

$$\begin{aligned} \sigma_{\Sigma}^b(\vec{\phi}) \vdash_{\Sigma} \sigma_{\Sigma}^b(\vec{\psi}) &\in G_{\Sigma}(\bigcup_{i < k} sq_{\Sigma}[\phi_i \approx \psi_i]) \\ &\quad (\text{by Congruence}) \\ &\subseteq G_{\Sigma}(\{\phi_i \vdash_{\Sigma} \psi_i, \psi_i \vdash_{\Sigma} \phi_i : i < k\}). \\ &\quad (\text{by Smoothness}) \end{aligned}$$

Assume, conversely, that the given condition holds. Then, for all σ^b in N^b , all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_i, \psi_i \in \mathbf{SEN}^b(\Sigma)$, $i < k$,

$$\begin{aligned} \sigma_{\Sigma}^b(\vec{\phi}) \vdash_{\Sigma} \sigma_{\Sigma}^b(\vec{\psi}) &\in G_{\Sigma}(\{\phi_i \vdash_{\Sigma} \psi_i, \psi_i \vdash_{\Sigma} \phi_i : i < k\}) \\ &\quad (\text{Hypothesis}) \\ &\subseteq G_{\Sigma}(\bigcup_{i < k} sq_{\Sigma}[\phi_i \approx \psi_i]). \\ &\quad (\text{by Monotonicity}) \end{aligned}$$

We conclude that $\mathfrak{G}$ has Congruence. ■

If a π -institution $\mathcal{I}$ is finitary, any $\mathcal{I}$ -structure must also be finitary. Therefore, for any Gentzen π -institution $\mathfrak{G}$, no infinitary $\mathfrak{G}$ -structure can be a full $\mathcal{I}$ -structure. It is this observation that leads to the following modification of the definition of full adequacy for finitary π -institutions.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. $\mathfrak{G}$ is said to be **fully adequate for $\mathcal{I}$** if one of the following two conditions holds:

- $\mathcal{I}$ has theorems, $\mathfrak{G}$ is of type 1 and, for every $\mathbf{F}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \mathbf{FStr}(\mathcal{I})$ if and only if $\mathbb{L}$ is finitary and $\mathbb{L} \in \mathbf{Str}(\mathfrak{G})$;
- $\mathcal{I}$ does not have theorems, $\mathfrak{G}$ is of type 0 and, for every $\mathbf{F}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L} \in \mathbf{FStr}(\mathcal{I})$ if and only if $\mathbb{L} \in \mathbf{Str}(\mathfrak{G})$ and $\mathbb{L}$ is finitary without theorems.

For the sequel we need a finitary adaptation of Proposition 1529. This is a characterization of full adequacy of a Gentzen system for a finitary π -institution $\mathcal{I}$.

Proposition 1537 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a finitary π -institution based on $\mathbf{F}$ and $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. $\mathfrak{G}$ is fully adequate for $\mathcal{I}$ if and only if*

1. $\mathbf{AlgSys}(\mathfrak{G}) = \mathbf{AlgSys}(\mathcal{I})$;
2. For all $\mathcal{A} \in \mathbf{AlgSys}(\mathcal{I})$, $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is the only finitary and reduced $\mathfrak{G}$ -structure on $\mathcal{A}$ (without theorems if $\mathcal{I}$ does not have any);
3. $\mathcal{I}$ has theorems and $\mathfrak{G}$ is of type 1 or $\mathcal{I}$ does not have theorems and $\mathfrak{G}$ is of type 0.

Proof: Assume $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. Then, by Proposition 1529, Conditions 1-3 hold, where in Condition 2 $\langle \mathcal{A}, \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is finitary by Proposition 114. Thus, the “only if” holds.

Assume, conversely, that Conditions 1-3 hold. Then, for all $\mathbf{F}$ -structures $\mathbb{L} = \langle \mathcal{A}, D \rangle$,

$$\begin{aligned}
 \mathbb{L} \in \mathbf{FStr}(\mathcal{I}) & \text{ iff } \mathcal{A}^* \in \mathbf{AlgSys}(\mathcal{I}), \mathcal{D}^* = \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}^*) \\
 & \text{ iff } \mathcal{A}^* \in \mathbf{AlgSys}(\mathfrak{G}) \text{ and } \langle \mathcal{A}^*, \mathcal{D}^* \rangle \in \mathbf{Str}(\mathfrak{G}) \\
 & \quad \text{finitary (w/o theorems if } \mathcal{I} \text{ does not have any)} \\
 & \text{ iff } \langle \mathcal{A}, \mathcal{D} \rangle \in \mathbf{Str}(\mathfrak{G}) \text{ finitary} \\
 & \quad \text{(w/o theorems if } \mathcal{I} \text{ does not have any)}.
 \end{aligned}$$

This, combined with Condition 3, gives that $\mathfrak{G}$ is fully adequate for $\mathcal{I}$. ■

20.5 IsoFull Adequacy and the DD Theorem

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and, for all $n < \omega$, $\Delta^n : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ a collection of natural transformations in N^b , with $n+1$ distinguished arguments. Set

$$\Delta = \{\Delta^n : n < \omega\}.$$

Given a π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$, based on $\mathbf{F}$, and $T \in \text{ThFam}(\mathcal{I})$, Δ is a **Parameterized Graded Deduction Detachment (PGDD) system for $\mathcal{I}$ over T** if, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_0, \dots, \phi_{n-1}, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$\psi \in C_\Sigma(T_\Sigma, \phi_0, \dots, \phi_{n-1}) \quad \text{iff} \quad \Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi] \leq T.$$

The left-to-right implication is the **Graded Deduction Property over T** and the right-to-left implication is the **Graded Detachment Property over T** .

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\Delta = \{\Delta^n : n < \omega\}$ in N^b . Define a family $r^{\Delta^n} = \{r_\Sigma^{\Delta^n}\}_{\Sigma \in |\mathbf{Sign}^b|}$ of Gentzen $\mathbf{F}$ -rules by setting, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$r_\Sigma^{\Delta^n} = \{ \{ \{ \phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi \}, \vdash_\Sigma \Delta_\Sigma^n(\phi_0, \dots, \phi_{n-1}, \psi, \vec{\chi}) \} : \phi, \psi, \vec{\chi} \in \mathbf{SEN}^b(\Sigma) \}.$$

Existence of a PGDD system Δ over a theory family T guarantees that the $\mathcal{I}$ -structure $\langle \mathcal{F}, C^T \rangle$ satisfies all Gentzen $\mathbf{F}$ -rules in r^{Δ^n} , $n < \omega$.

Lemma 1538 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $T \in \text{ThFam}(\mathcal{I})$ and $\Delta = \{\Delta^n : n < \omega\}$ a PGDD system for $\mathcal{I}$ over T . Then, for all $n < \omega$,*

$$\langle \mathcal{F}, \text{ThFam}(\mathcal{I})^T \rangle \models r^{\Delta^n}.$$

Proof: Suppose $\Sigma \in |\mathbf{Sign}^b|$, $\vec{\phi}, \psi \in \mathbf{SEN}^b(\Sigma)$, such that $\psi \in C_\Sigma^T(\phi_0, \dots, \phi_{n-1})$. Equivalently, we get $\psi \in C_\Sigma(T_\Sigma, \phi_0, \dots, \phi_{n-1})$. By hypothesis, since Δ is a PGDD system for $\mathcal{I}$ over T , we get $\Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi] \leq T$. In particular, we get, for all $\vec{\chi} \in \mathbf{SEN}^b(\Sigma)$, $\Delta_\Sigma^n(\phi_0, \dots, \phi_{n-1}, \psi, \vec{\chi}) \subseteq T_\Sigma$. Equivalently, $\vdash_\Sigma \Delta_\Sigma^n(\phi_0, \dots, \phi_{n-1}, \psi, \vec{\chi}) \in C_\Sigma^T(\emptyset)$. Thus, $\langle \mathcal{F}, \text{ThFam}(\mathcal{I})^T \rangle \models r^{\Delta^n}$. ■

We show, next, that all Gentzen $\mathbf{F}$ -rules are preserved by biological morphisms between $\mathbf{F}$ -structures.

Lemma 1539 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{A}' = \langle \mathbf{A}', \langle F', \alpha' \rangle \rangle$ $\mathbf{F}$ -algebraic systems, $\mathbb{L} = \langle \mathcal{A}, D \rangle$, $\mathbb{L}' = \langle \mathcal{A}', D' \rangle$ two $\mathbf{F}$ -structures and $\langle H, \gamma \rangle : \mathbb{L} \vdash \mathbb{L}'$ a biological morphism. Then, for all $\Sigma \in |\mathbf{Sign}^b|$, every $\mathbf{F}$ -sequent $\Psi \vdash_\Sigma \psi$ and every Gentzen $\mathbf{F}$ -rule $r := \langle \{ \Phi_i \vdash_\Sigma \phi_i : i \in I \}, \Phi \vdash_\Sigma \phi \rangle$,*

- (a) $\mathbb{L} \models_{\Sigma} \Psi \vdash_{\Sigma} \psi$ if and only if $\mathbb{L}' \models_{\Sigma} \Psi \vdash_{\Sigma} \psi$;
 (b) $\mathbb{L} \models_{\Sigma} r$ if and only if $\mathbb{L}' \models_{\Sigma} r$.

Proof:

- (a) We have

$$\begin{aligned}
 \mathbb{L} \models_{\Sigma} \Psi \vdash_{\Sigma} \psi & \text{ iff } \alpha_{\Sigma}(\psi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Psi)) \\
 & \text{ iff } \gamma_{F(\Sigma)}(\alpha_{\Sigma}(\psi)) \in D'_{H(F(\Sigma))}(\gamma_{H(F(\Sigma))}(\alpha_{\Sigma}(\Psi))) \\
 & \text{ iff } \alpha'_{\Sigma}(\psi) \in D'_{F'(\Sigma)}(\alpha'_{\Sigma}(\Psi)) \\
 & \text{ iff } \mathbb{L}' \models_{\Sigma} \Psi \vdash_{\Sigma} \psi.
 \end{aligned}$$

- (b) This part follows easily from Part (a).

$$\begin{aligned}
 (\Rightarrow) & \text{ If } \alpha'_{\Sigma}(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_{\Sigma}(\Phi_i)), i \in I, \text{ then } \alpha_{\Sigma}(\phi_i) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)), \\
 & i \in I, \text{ whence } \alpha_{\Sigma}(\phi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)). \text{ So } \alpha'_{\Sigma}(\phi) \in D'_{F'(\Sigma)}(\alpha'_{\Sigma}(\Phi)). \\
 (\Leftarrow) & \text{ If } \alpha_{\Sigma}(\phi_i) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi_i)), i \in I, \text{ then } \alpha'_{\Sigma}(\phi_i) \in D'_{F'(\Sigma)}(\alpha'_{\Sigma}(\Phi_i)), \\
 & i \in I, \text{ whence } \alpha'_{\Sigma}(\phi) \in D'_{F'(\Sigma)}(\alpha'_{\Sigma}(\Phi_i)), i \in I, \text{ and, therefore,} \\
 & \alpha_{\Sigma}(\phi) \in D_{F(\Sigma)}(\alpha_{\Sigma}(\Phi)).
 \end{aligned}$$

■

Some of the elements of the discussion that follows will be revisited in Chapter 21 on $\mathcal{I}$ -operators in a more general context. We give a preview of a few results here, as needed, restricting the discussion mostly to protoalgebraic π -institutions. This restriction will be lifted in Chapter 21, where the concepts will be revisited in full generality.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Given an $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and an $\mathcal{I}$ -filter family $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, we let

$$[T] = \{T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)\},$$

the **equi-Leibniz class** of T . If $[T]$ has a smallest member, it is denoted by T^* . T is called a **Leibniz filter** if $T = T^*$, i.e., if it is the smallest filter in its equi-Leibniz class. We denote by $\mathbf{FiFam}^{\mathcal{I}*}(\mathcal{A})$ the collection of all Leibniz $\mathcal{I}$ -filter families of $\mathcal{A}$.

We show that Leibniz filter families are preserved under inverse surjective morphisms with isomorphic functor components. For a more general result, see Corollary 1612 in Chapter 21.

Lemma 1540 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism. Then*

$$\gamma^{-1}(\mathbf{FiFam}^{\mathcal{I}*}(\mathcal{B})) \subseteq \mathbf{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: Let $T' \in \text{FiFam}^{\mathcal{I}^*}(\mathcal{B})$ and $T = \gamma^{-1}(T')$. Then $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Moreover, $\Omega^{\mathcal{A}}(T) = \Omega^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'))$. Consider $X \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $X \in [T]$, i.e., such that $\Omega^{\mathcal{A}}(X) = \Omega^{\mathcal{A}}(T)$. Then, since $\Omega^{\mathcal{A}}(T) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'))$, $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with X . Hence $\gamma(X) \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$. Furthermore,

$$\gamma^{-1}(\Omega^{\mathcal{B}}(\gamma(X))) = \Omega^{\mathcal{A}}(\gamma^{-1}(\gamma(X))) = \Omega^{\mathcal{A}}(X) = \Omega^{\mathcal{A}}(T) = \gamma^{-1}(\Omega^{\mathcal{B}}(T')).$$

So $\Omega^{\mathcal{B}}(\gamma(X)) = \Omega^{\mathcal{B}}(T')$. Thus, since $T' \in \text{FiFam}^{\mathcal{I}^*}(\mathcal{B})$, $T' \leq \gamma(X)$. Now we get, taking again into account the compatibility of $\text{Ker}(\langle H, \gamma \rangle)$ with X , $T = \gamma^{-1}(T') \leq \gamma^{-1}(\gamma(X)) = X$. This proves that $T \in \text{FiFam}^{\mathcal{I}^*}(\mathcal{A})$. ■

As a corollary, we obtain

Corollary 1541 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism. Then, for all $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that T'^* exists,*

$$\gamma^{-1}(T'^*) = \gamma^{-1}(T')^*.$$

Proof: Suppose $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that T'^* exists. Then $\gamma^{-1}(T'^*) \in \text{FiFam}^{\mathcal{I}^*}(\mathcal{A})$, by Lemma 1540. Hence, we have

$$\Omega^{\mathcal{A}}(\gamma^{-1}(T'^*)) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'^*)) = \gamma^{-1}(\Omega^{\mathcal{B}}(T')) = \Omega^{\mathcal{A}}(\gamma^{-1}(T')).$$

Thus, since $\gamma^{-1}(T'^*)$ is Leibniz, we get $\gamma^{-1}(T'^*) = \gamma^{-1}(T')^*$. ■

Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. An $\mathcal{I}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, with $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, is called **isofull** if it is full and F is an isomorphism.

We show, next, that, if $\Delta = \{\Delta^n : n < \omega\}$ is a PGDD system for $\mathcal{I}$ over every $\mathcal{I}$ -theory family, then every isofull $\mathcal{I}$ -structure satisfies the Gentzen $\mathbf{F}$ -rules r^{Δ^n} .

Lemma 1542 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$ and $\Delta = \{\Delta^n : n < \omega\}$ a PGDD system for $\mathcal{I}$ over every Leibniz $\mathcal{I}$ -theory family. Then every isofull $\mathcal{I}$ -structure satisfies r^{Δ^n} , for all $n < \omega$.*

Proof: By Lemma 1539, it suffices to show that, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with F an isomorphism, and every $n < \omega$,

$$\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \models r^{\Delta^n}.$$

Let $T = C^{\mathcal{I}, \mathcal{A}}(\emptyset)$ be the smallest $\mathcal{I}$ -filter family on $\mathcal{A}$. By the Correspondence Theorem for protoalgebraic π -institutions, we have $\alpha^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) =$

$\text{ThFam}(\mathcal{I})^{\alpha^{-1}(T)}$. Since T is least among all $\mathcal{I}$ -filter families of $\mathcal{A}$, we have $T \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Therefore, by Lemma 1540, $\alpha^{-1}(T) \in \text{ThFam}^*(\mathcal{I})$. Thus, by the hypothesis and Lemma 1538, we get that $\langle \mathcal{F}, \text{ThFam}(\mathcal{I})^{\alpha^{-1}(T)} \rangle \models r^{\Delta^n}$. However, $\langle F, \alpha \rangle : \langle \mathcal{F}, \text{ThFam}(\mathcal{I})^{\alpha^{-1}(T)} \rangle \vdash \langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle$ is a bilogical morphism, whence, by Lemma 1539, we get $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rangle \models r^{\Delta^n}$. ■

In the next lemma, it is shown that, in case the π -institution $\mathcal{I}$ is syntactically protoalgebraic, the witnessing transformations may be used to generate Leibniz filter families.

Lemma 1543 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution based on $\mathbf{F}$, with witnessing transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then*

$$T^* = C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow \mathcal{A}}{I}_\Sigma[\phi, \psi] : \Sigma \in |\mathbf{Sign}|, \langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathcal{A}}(T) \}).$$

Proof: Let $\mathcal{A}$ be an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. We set

$$\tilde{T} = C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow \mathcal{A}}{I}_\Sigma[\phi, \psi] : \Sigma \in |\mathbf{Sign}|, \langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathcal{A}}(T) \}).$$

Our goal is to show that $T^* = \tilde{T}$. First, let $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T' \in [T]$, i.e., $\Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Then, we have, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$,

$$\begin{aligned} \langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathcal{A}}(T) & \text{ iff } \langle \phi, \psi \rangle \Omega_\Sigma^{\mathcal{A}}(T') \\ & \text{ iff } \overset{\leftrightarrow \mathcal{A}}{I}_\Sigma[\phi, \psi] \leq T'. \end{aligned}$$

We conclude that $\tilde{T} \leq T^*$ and, by protoalgebraicity, $\Omega^{\mathcal{A}}(\tilde{T}) \leq \Omega^{\mathcal{A}}(T^*)$. On the other hand, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \Omega_\Sigma^{\mathcal{A}}(T)$, $\overset{\leftrightarrow \mathcal{A}}{I}_\Sigma[\phi, \psi] \leq \tilde{T}$. Thus, $\Omega^{\mathcal{A}}(T^*) = \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(\tilde{T})$. Therefore, $\Omega^{\mathcal{A}}(\tilde{T}) = \Omega^{\mathcal{A}}(T^*)$ and, since we showed that $\tilde{T} \leq T^*$, we get by the minimality property of T^* in $[T]$, $T^* = \tilde{T}$. ■

Corollary 1544 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution based on $\mathbf{F}$, with witnessing transformations $I^b : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then $T \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A})$ if and only if, there exists $X \leq \text{SEN}^2$, such that*

$$T = C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow \mathcal{A}}{I}_\Sigma[\phi, \psi] : \Sigma \in |\mathbf{Sign}|, \langle \phi, \psi \rangle \in X_\Sigma \}).$$

Proof: For the left-to-right implication, assume $T \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Take $X = \Omega^{\mathcal{A}}(T)$. Then we have, using the hypothesis and Lemma 1543, $T = T^* = C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow \mathcal{A}}{I}_\Sigma[\phi, \psi] : \Sigma \in |\mathbf{Sign}|, \langle \phi, \psi \rangle \in X_\Sigma \})$.

Suppose, conversely, that $T = C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow}{I}_{\Sigma}^{\mathcal{A}}[\phi, \psi] : \Sigma \in |\mathbf{Sign}|, \langle \phi, \psi \rangle \in X_{\Sigma} \})$, for some $X \leq \mathbf{SEN}$. Then, for all $\Sigma \in |\mathbf{Sign}|$ and all $\phi, \psi \in \mathbf{SEN}(\Sigma)$, $\langle \phi, \psi \rangle \in X_{\Sigma}$ implies $\overset{\leftrightarrow}{I}_{\Sigma}^{\mathcal{A}}[\phi, \psi] \leq T$. Thus, $\langle \phi, \psi \rangle \in \Omega_{\Sigma}^{\mathcal{A}}(T)$. Therefore, by Lemma 1543, $T \leq C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow}{I}_{\Sigma}^{\mathcal{A}}[\phi, \psi] : \Sigma \in |\mathbf{Sign}|, \langle \phi, \psi \rangle \in X_{\Sigma} \}) = T^*$. Since, it is always the case that $T^* \leq T$, we get that $T = T^*$ and $T \in \mathbf{FiFam}^{\mathcal{I}^*}(\mathcal{A})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. A collection $\Delta = \{ \Delta^n : n < \omega \}$, where $\Delta^n : (\mathbf{SEN}^b)^{\omega} \rightarrow \mathbf{SEN}$ in N^b , with $n+1$ distinguished arguments, is called **Leibniz generating over $\mathcal{I}$** if, for all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \psi \in \mathbf{SEN}^b(\Sigma)$,

$$C(\Delta_{\Sigma}^n[\vec{\phi}, \psi]) \in \mathbf{ThFam}^*(\mathcal{I}),$$

for all $n < \omega$.

We show that, for a syntactically protoalgebraic π -institution $\mathcal{I}$, the property of being Leibniz generating over $\mathcal{I}$, transfers, in certain sense, to the filter families over arbitrary $\mathbf{F}$ -algebraic systems.

Lemma 1545 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution based on $\mathbf{F}$, with witnessing transformations $I^b : (\mathbf{SEN}^b)^{\omega} \rightarrow \mathbf{SEN}^b$ in N^b , and $\Delta : (\mathbf{SEN}^b)^{\omega} \rightarrow \mathbf{SEN}^b$ a Leibniz generating collection in N^b , with $n+1$ distinguished arguments. Then for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\Sigma \in |\mathbf{Sign}|$ and $\vec{\phi}, \psi \in \mathbf{SEN}(\Sigma)$,*

$$C^{\mathcal{I}, \mathcal{A}}(\Delta_{\Sigma}^{\mathcal{A}}[\vec{\phi}, \psi]) \in \mathbf{FiFam}^{\mathcal{I}^*}(\mathcal{A}).$$

Proof: By hypothesis, Δ is Leibniz generating. Hence, for all $\Sigma \in |\mathbf{Sign}^b|$, $\vec{\phi}, \psi \in \mathbf{SEN}^b(\Sigma)$, $C(\Delta_{\Sigma}[\vec{\phi}, \psi]) \in \mathbf{ThFam}^*(\mathcal{I})$. Thus, by Corollary 1544, there exists $X \leq (\mathbf{SEN}^b)^2$, such that

$$C(\Delta_{\Sigma}[\vec{\phi}, \psi]) = C(\bigcup \{ \overset{\leftrightarrow}{I}_{\Sigma'}^b[\phi', \psi'] : \Sigma' \in |\mathbf{Sign}^b|, \langle \phi', \psi' \rangle \in X_{\Sigma'} \}).$$

Now we get

$$\begin{aligned} & C^{\mathcal{I}, \mathcal{A}}(\Delta_{F(\Sigma)}^{\mathcal{A}}[\alpha_{\Sigma}(\vec{\phi}), \alpha_{\Sigma}(\psi)]) \\ &= C^{\mathcal{I}, \mathcal{A}}(\alpha(\Delta_{\Sigma}[\vec{\phi}, \psi])) \\ &= C^{\mathcal{I}, \mathcal{A}}(\alpha(C(\bigcup \{ \overset{\leftrightarrow}{I}_{\Sigma'}^b[\phi', \psi'] : \Sigma' \in |\mathbf{Sign}^b|, \langle \phi', \psi' \rangle \in X_{\Sigma'} \}))) \\ &= C^{\mathcal{I}, \mathcal{A}}(\alpha(\bigcup \{ \overset{\leftrightarrow}{I}_{\Sigma'}^b[\phi', \psi'] : \Sigma' \in |\mathbf{Sign}^b|, \langle \phi', \psi' \rangle \in X_{\Sigma'} \})) \\ &= C^{\mathcal{I}, \mathcal{A}}(\bigcup \{ \overset{\leftrightarrow}{I}_{F(\Sigma')}^{\mathcal{A}}[\alpha_{\Sigma'}(\phi'), \alpha_{\Sigma'}(\psi')] : \Sigma' \in |\mathbf{Sign}^b|, \\ & \quad \langle \alpha_{\Sigma'}(\phi'), \alpha_{\Sigma'}(\psi') \rangle \in \alpha_{\Sigma'}(X_{\Sigma'}) \}). \end{aligned}$$

Thus, taking into account the surjectivity of $\langle F, \alpha \rangle$, we obtain, using again Corollary 1544, that for all $\Sigma \in |\mathbf{Sign}|$ and all $\vec{\phi}, \psi \in \mathbf{SEN}(\Sigma)$, $C^{\mathcal{I}, \mathcal{A}}(\Delta_{\Sigma}^{\mathcal{A}}[\vec{\phi}, \psi]) \in \mathbf{FiFam}^{\mathcal{I}^*}(\mathcal{A})$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. A PGDD system $\Delta = \{\Delta^n : n < \omega\}$ for $\mathcal{I}$ is called **Leibniz generating** if Δ^n is Leibniz generating, for every $n < \omega$.

It is not difficult to see that Leibniz generating PGDD systems have a graded Modus Ponens property, in the sense detailed in the following

Lemma 1546 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. If $\Delta = \{\Delta^n : n < \omega\}$ is a PGDD system for $\mathcal{I}$ over every Leibniz theory family, then, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\vec{\phi}, \psi \in \mathbf{SEN}^b(\Sigma)$,*

$$\psi \in C_\Sigma(\Delta_\Sigma^n[\vec{\phi}, \psi], \vec{\phi}).$$

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$ and $\vec{\phi}, \psi \in \mathbf{SEN}^b(\Sigma)$ and set $T = C(\Delta_\Sigma^n[\vec{\phi}, \psi])$. By hypothesis, $T \in \mathbf{ThFam}^*(\mathcal{I})$. Since Δ is a PGDD system for $\mathcal{I}$ over every Leibniz theory family, we get

$$\psi \in C_\Sigma(T_\Sigma, \vec{\phi}) \quad \text{iff} \quad \Delta_\Sigma^n[\vec{\phi}, \psi] \leq C(T) = T.$$

Thus, since the right hand side of the equivalence holds, we obtain $\psi \in C_\Sigma(T_\Sigma, \vec{\phi}) = C_\Sigma(C_\Sigma(\Delta_\Sigma^n[\vec{\phi}, \psi]), \vec{\phi}) = C_\Sigma(\Delta_\Sigma^n[\vec{\phi}, \psi], \vec{\phi})$. $\blacksquare$

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\Delta : (\mathbf{SEN}^b)^\omega \rightarrow \mathbf{SEN}^b$ in N^b , with a single distinguished argument. We say that Δ **isodefinies Leibniz filter families over $\mathcal{I}$** if, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with F an isomorphism, all $T \in \mathbf{FiFam}^\mathcal{I}(\mathcal{A})$ and all $\Sigma \in |\mathbf{Sign}|$,

$$T_\Sigma^* = \{\phi \in \mathbf{SEN}(\Sigma) : \Delta_\Sigma^A[\phi] \leq T\}.$$

We show, next, that, in a syntactically protoalgebraic π -institution $\mathcal{I}$, which has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over every Leibniz theory family, the 0-th component Δ^0 does isodefine Leibniz filter families over $\mathcal{I}$.

A couple of lemmas are needed first.

Lemma 1547 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T, T' \in \mathbf{FiFam}^\mathcal{I}(\mathcal{A})$, $T \leq T'$ implies $T^* \leq T'^*$.*

Proof: Suppose $T, T' \in \mathbf{FiFam}^\mathcal{I}(\mathcal{A})$, such that $T \leq T'$. By protoalgebraicity of $\mathcal{I}$, we get

$$\Omega^A(T \cap T'^*) = \Omega^A(T) \cap \Omega^A(T'^*) = \Omega^A(T) \cap \Omega^A(T') = \Omega^A(T).$$

Thus $T^* \leq T \cap T'^* \leq T'^*$. $\blacksquare$

Lemma 1548 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a protoalgebraic π -institution based on $\mathbf{F}$. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \text{FStr}(\mathcal{I}) \quad \text{iff} \quad T \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A}).$$

Proof: We have, using Theorem 1432 and protoalgebraicity, $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \rangle \in \text{FStr}(\mathcal{I})$ if and only if

$$\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T = \{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\}.$$

Since, under protoalgebraicity, it always holds that

$$\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq \{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\},$$

it suffices to show that

$$T \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A}) \quad \text{iff} \quad \begin{array}{l} \text{for all } T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}), \\ \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \text{ implies } T \leq T'. \end{array}$$

The right to left implication is trivial, since the condition on the right implies that T is smallest among all filter families sharing the same Leibniz congruence system with T . For the converse, suppose T is a Leibniz filter family of $\mathcal{A}$ and that $\Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')$. Then, using protoalgebraicity, we get $\Omega(T \cap T') = \Omega^{\mathcal{A}}(T) \cap \Omega^{\mathcal{A}}(T') = \Omega^{\mathcal{A}}(T)$. Thus, we conclude that $T = T^* \leq T \cap T' \leq T'$. ■

Theorem 1549 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic π -institution based on $\mathbf{F}$, with $\Delta = \{\Delta^n : n < \omega\}$ a Leibniz generating PGDD system for $\mathcal{I}$ over every Leibniz theory family. Then Δ^0 isodefinies Leibniz filter families over $\mathcal{I}$.*

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system, with F an isomorphism, and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\Sigma \in |\mathbf{Sign}|$ and $\phi \in \text{SEN}(\Sigma)$.

Suppose, first, that $\Delta_{\Sigma}^0[\phi] \leq T$. Let $T' = C^{\mathcal{I}, \mathcal{A}}(\Delta_{\Sigma}^0[\phi])$. By hypothesis and Lemma 1545, $T' \in \text{FiFam}^{\mathcal{I}*}(\mathcal{A})$. Since $T' \leq T$, by Lemma 1547, $T' \leq T^*$. Hence, $\Delta_{\Sigma}^0[\phi] \leq T^*$. Therefore, by Lemma 1546, $\phi \in T_{\Sigma}^*$.

Suppose, conversely, that $\phi \in T_{\Sigma}^*$. Then, by definition, the $\mathcal{I}$ -structure $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*} \rangle$ satisfies $\vdash_{\Sigma} \phi$. By Lemma 1548, $\langle \mathcal{A}, \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*} \rangle \in \text{FStr}(\mathcal{I})$. Thus, by Lemma 1542, $\langle \mathcal{A}, \text{FiFam}^{\mathcal{A}}(\mathcal{A})^{T^*} \rangle$ satisfies r^{Δ^0} . Hence, for all $\Sigma' \in |\mathbf{Sign}|$, all $f \in \mathbf{Sign}(\Sigma, \Sigma')$ and all $\tilde{\chi} \in \text{SEN}(\Sigma')$, $\Delta_{\Sigma'}^0(\text{SEN}(f)(\phi), \tilde{\chi}) \in T_{\Sigma'}^* \subseteq T_{\Sigma'}$. We conclude that $\Delta_{\Sigma}^0[\phi] \leq T$. ■

We are ready now to prove one half of the main result of this section. We would like to show that, for a syntactically protoalgebraic finitary π -institution, the existence of a Leibniz generating PGDD system over all

Leibniz theory families implies the existenc of an isofully adequate Gentzen π -institution.

We define that institution, first, preceding the statement of the theorem that involves it in its proof.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, with $\Delta = \{\Delta^n : n < \omega\}$ in N^b , where Δ^n has $n + 1$ distinguished arguments, and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. Define:

- $Ax^{\mathcal{I}} = \{Ax_{\Sigma}^{\mathcal{I}}\}_{\Sigma \in |\mathbf{Sign}^b|}$, where, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$Ax_{\Sigma}^{\mathcal{I}} = \{\Phi \vdash_{\Sigma} \phi : \phi \in C_{\Sigma}(\Phi)\};$$

- $Ir^{\mathcal{I}} = \{Ir_{\Sigma}^{\mathcal{I}}\}_{\Sigma \in |\mathbf{Sign}^b|}$, where, for all $\Sigma \in |\mathbf{Sign}^b|$,

$$Ir_{\Sigma}^{\mathcal{I}} = \{r_{\Sigma}^{\Delta^n} : n < \omega\}.$$

Set $R^{\mathcal{I}} = Ax^{\mathcal{I}} \cup Ir^{\mathcal{I}}$ and let

$$\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$$

be the Gentzen π -institution generated by $R^{\mathcal{I}}$ (recall that $G^{\mathcal{I}}$ is required to be a structural closed system on $\text{Seq}(\mathbf{F})$ and, therefore, it is assumed to satisfy, by default, (Axiom), (Weakening) and (Cut)).

Theorem 1550 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over all Leibniz theory families, then it has an isofully adequate Gentzen π -institution, namely the Gentzen π -institution $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$.*

Proof: We must show that, for every $\mathbf{F}$ -structure $\mathbb{L} = \langle \mathcal{A}, D \rangle$, where $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, with F an isomorphism, we have

$$\mathbb{L} \in \text{Str}(\mathfrak{G}^{\mathcal{I}}) \quad \text{iff} \quad \mathbb{L} \in \text{FStr}(\mathcal{I}).$$

Suppose, first, that $\mathbb{L} \in \text{FStr}(\mathcal{I})$. Then $\mathbb{L}$ is, in particular, an $\mathcal{I}$ -structure. Therefore, it satisfies $Ax^{\mathcal{I}}$. Moreover, by Lemma 1542, $\mathbb{L}$ satisfies r^{Δ^n} , for all $n < \omega$. Hence, it also satisfies $Ir^{\mathcal{I}}$. We conclude that $\mathbb{L} \in \text{Str}(\mathfrak{G}^{\mathcal{I}})$.

Suppose, conversely, that $\mathbb{L} \in \text{Str}(\mathfrak{G}^{\mathcal{I}})$. Clearly, $\mathbb{L} \in \text{Str}(\mathcal{I})$, since it satisfies $Ax^{\mathcal{I}}$. So it suffices to show that it is also full. Assume, to the contrary, that $\mathbb{L}$ is not full and let $T = D(\emptyset)$. Since $\mathcal{I}$ is protoalgebraic and $\mathbb{L}$ is not full, we have, using Lemma 1548, $\mathcal{D} \subsetneq \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*}$. Consider $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*} - \mathcal{D}$. Then we get $D(T') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})^{T^*}$ and $T^* \leq T' \not\leq D(T')$. Let $\Sigma \in |\mathbf{Sign}|$, $\phi \in \text{SEN}(\Sigma)$, such that $\phi \in D_{\Sigma}(T') - T'_{\Sigma}$. Then, there exists $\Phi \subseteq_f T'_{\Sigma}$, such that $\phi \in D_{\Sigma}(\Phi)$. Since $\mathbb{L}$ satisfies $Ir^{\mathcal{I}}$, we get $\Delta_{\Sigma}^n[\Phi, \phi] \leq T$. But Δ is also Leibniz generating, whence, by Lemma 1545,

$D(\Delta_\Sigma^n[\Phi, \phi]) \in \text{FiFam}^{\mathcal{I}^*}(\mathcal{A})$. Therefore, by Lemma 1547, $\Delta_\Sigma^n[\Phi, \phi] \leq T^*$. Now we get $\phi \in D_\Sigma(T'_\Sigma, \Phi) \subseteq D_\Sigma(T'_\Sigma) = T'_\Sigma$, which contradicts our assumption. Therefore, $\mathbb{L}$ is also full, as was to be shown. ■

Suppose, now, that $\mathcal{I}$ is a syntactically protoalgebraic, finitary π -institution with an isofully adequate Gentzen π -institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$. Then, for all $\langle \mathcal{F}, D \rangle \in \text{Str}(\mathfrak{G})$, we must have $\langle \mathcal{F}, D \rangle \in \text{FStr}(\mathcal{I})$ and, therefore, taking into account Lemma 1548, we get that $\mathcal{D} = \text{ThFam}(\mathcal{I})^T$, where $T \in \text{ThFam}^*(\mathcal{I})$. We denote by

$$h^{\mathfrak{G}} : \text{Str}^{\mathfrak{G}}(\mathcal{F}) \rightarrow \text{ThFam}^*(\mathcal{I})$$

the bijection that is established by this association, which is, in addition an order isomorphism.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{G} = \langle \mathbf{F}, G \rangle$ a Gentzen π -institution based on $\mathbf{F}$. Given a theory family $\Gamma \in \text{ThFam}(\mathfrak{G})$, recall the $\mathbf{F}$ -structure $\mathbb{L}^\Gamma = \langle \mathcal{F}, D^\Gamma \rangle$, which was shown in Lemma 1521 to be a $\mathfrak{G}$ -structure. For notational purposes, given $\Sigma \in |\mathbf{Sign}^b|$, $\phi_0, \dots, \phi_{n-1}, \psi \in \text{SEN}^b(\Sigma)$, let us write

$$\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi] := \mathbb{L}^{G(\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi)},$$

where, as usual, $G(\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi)$ denotes the least theory family of $\mathfrak{G}$ including the $\mathbf{F}$ -sequent $\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi$.

We call the Gentzen π -institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$ **transformational** if, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_0, \dots, \phi_{n-1}, \psi \in \text{SEN}^b(\Sigma)$,

$$h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi]) = C(\Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi]),$$

for some $\Delta^n : (\text{SEN}^b)^\omega \rightarrow \text{SEN}^b$ in N^b , with $n+1$ distinguished arguments.

We can show that the isofully adequate Gentzen π -institution $\mathfrak{G}^{\mathcal{I}}$ associated with a syntactically protoalgebraic finitary π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ that has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over all Leibniz theory families, as in Theorem 1550, is, in fact, a transformational Gentzen π -institution.

Theorem 1551 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has a Leibniz generating PGDD system $\Delta = \{\Delta^n : n < \omega\}$ over all Leibniz theory families, then the isofully adequate Gentzen π -institution $\mathfrak{G}^{\mathcal{I}} = \langle \mathbf{F}, G^{\mathcal{I}} \rangle$ for $\mathcal{I}$ is transformational.*

Proof: Let $\Sigma \in |\mathbf{Sign}^b|$, $\phi_0, \dots, \phi_{n-1}, \psi \in \text{SEN}^b(\Sigma)$ and denote

$$T := C(\Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi]).$$

By hypothesis, we have $T \in \text{ThFam}^*(\mathcal{I})$. Since T is a Leibniz $\mathcal{I}$ -theory family and Δ is a PGDD system over all Leibniz theory families, T is closed

under all axioms and rules of $\mathfrak{G}^{\mathcal{I}}$. Moreover, if $\phi_0, \dots, \phi_{n-1} \in T_{\Sigma}$, then, since $\Delta_{\Sigma}^n[\phi_0, \dots, \phi_{n-1}, \psi] \leq T$, we get, by Lemma 1546, $\psi \in T_{\Sigma}$. Hence, T is a theory family of the $\mathbf{F}$ -structure $\mathfrak{G}^{\mathcal{I}}[\phi_0, \dots, \phi_{n-1}, \psi]$. Since, by definition, $h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi])$ is its least theory family, we get that $h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi]) \leq C(\Delta_{\Sigma}^n[\phi_0, \dots, \phi_{n-1}, \psi])$.

On the other hand, by definition,

$$\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi \in G_{\Sigma}^{\mathcal{I}}(\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi),$$

whence, writing $\mathfrak{G}^{\mathcal{I}}[\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi] := \langle \mathcal{F}, D \rangle$, we get $\psi \in D_{\Sigma}(\phi_0, \dots, \phi_{n-1})$. Recalling that every full model is structural, we get, for all $\Sigma' \in |\mathbf{Sign}^b|$, $f \in \mathbf{Sign}^b(\Sigma, \Sigma')$,

$$\text{SEN}^b(f)(\psi) \in D_{\Sigma'}(\text{SEN}^b(f)(\phi_0), \dots, \text{SEN}^b(f)(\phi_{n-1})).$$

Thus, since $\mathfrak{G}^{\mathcal{I}}$ satisfies r^{Δ^n} , we get, for all $\tilde{\chi} \in \text{SEN}^b(\Sigma')$,

$$\Delta_{\Sigma'}(\text{SEN}^b(f)(\phi_0), \dots, \text{SEN}^b(f)(\phi_{n-1}), \text{SEN}^b(f)(\psi), \tilde{\chi}) \subseteq D_{\Sigma'}(\emptyset),$$

i.e., that $\Delta_{\Sigma}^n[\phi_0, \dots, \phi_{n-1}, \psi] \leq h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi])$. We now conclude that

$$C(\Delta_{\Sigma}^n[\phi_0, \dots, \phi_{n-1}, \psi]) \leq h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi]).$$

Therefore, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_0, \dots, \phi_{n-1}, \psi \in \text{SEN}^b(\Sigma)$,

$$h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_{\Sigma} \psi]) = C(\Delta_{\Sigma}^n[\phi_0, \dots, \phi_{n-1}, \psi]),$$

showing that $\mathfrak{G}^{\mathcal{I}}$ is transformational. ■

Finally, we show that, for a syntactically protoalgebraic, finitary π -institution $\mathcal{I}$, the existence of an isofully adequate, transformational Gentzen π -institution $\mathfrak{G}$ for $\mathcal{I}$ implies that $\mathcal{I}$ has a Leibniz generating PGDD system over every Leibniz theory family.

Theorem 1552 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a syntactically protoalgebraic, finitary π -institution based on $\mathbf{F}$. If $\mathcal{I}$ has an isofully adequate transformational Gentzen π -institution, then $\mathcal{I}$ has a Leibniz generating PGDD system over every Leibniz theory family.*

Proof: Suppose that $\mathcal{I}$ has an isofully adequate transformational Gentzen π -institution $\mathfrak{G} = \langle \mathbf{F}, G \rangle$. Thus, by definition, for all $n < \omega$, all $\Sigma \in |\mathbf{Sign}^b|$ and all $\phi_0, \dots, \phi_{n-1}, \psi \in \text{SEN}^b(\Sigma)$, there exists a collection $\Delta^n : (\text{SEN}^b)^{\omega} \rightarrow \text{SEN}^b$ in N^b , with $n + 1$ distinguished arguments, such that

$$h^{\mathfrak{G}}(\mathfrak{G}[\phi_0, \dots, \phi_{n-1}, \psi]) = C(\Delta_{\Sigma}^n[\phi_0, \dots, \phi_{n-1}, \psi]).$$

By the fact that $h^{\mathfrak{G}}$ maps, by hypothesis and Lemma 1548, into $\text{ThFam}^*(\mathcal{I})$, ensures that $\Delta = \{\Delta^n : n < \omega\}$ is Leibniz generating. So it suffices to show

that Δ is a PGDD system for $\mathcal{I}$ over every Leibniz theory family. To this end, assume that $T \in \text{ThFam}^*(\mathcal{I})$, $n < \omega$, $\Sigma \in |\mathbf{Sign}^b|$ and $\phi_0, \dots, \phi_{n-1}, \psi \in \text{SEN}^b(\Sigma)$. We must show that

$$\psi \in C_\Sigma(T_\Sigma, \phi_0, \dots, \phi_{n-1}) \quad \text{iff} \quad \Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi] \leq T.$$

We have

$$\begin{aligned} \psi \in C_\Sigma(T_\Sigma, \phi_0, \dots, \phi_{n-1}) & \quad \text{iff} \quad \psi \in C_\Sigma^T(\phi_0, \dots, \phi_{n-1}) \\ & \quad \text{iff} \quad \mathfrak{G}[\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi] \leq \mathcal{C}^T \\ & \quad \text{iff} \quad h^\mathfrak{G}(\mathfrak{G}(\phi_0, \dots, \phi_{n-1} \vdash_\Sigma \psi)) \leq T \\ & \quad \text{iff} \quad C(\Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi]) \leq T \\ & \quad \text{iff} \quad \Delta_\Sigma^n[\phi_0, \dots, \phi_{n-1}, \psi] \leq T. \end{aligned}$$

We conclude that Δ is indeed Leibniz generating PGDD system for $\mathcal{I}$ over every Leibniz theory family. $\blacksquare$

In conclusion, we have

Theorem 1553 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system. A syntactically protoalgebraic, finitary π -institution $\mathcal{I} = \langle \mathbf{F}, C \rangle$ based on $\mathbf{F}$ has an isofully adequate transformational Gentzen π -institution if and only if it has a Leibniz generating PGDD system over every Leibniz theory family.*

Proof: The “if” was proven in Theorems 1550 and 1551. The “only if” is by Theorem 1552. $\blacksquare$

Chapter 21

Operators on π -Institutions

21.1 $\mathcal{I}$ -Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system.

An $\mathcal{I}$ -operator on $\mathcal{A}$ is a map

$$O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A}),$$

where $\text{EqvFam}(\mathcal{A})$ is the collection of equivalence families on $\mathcal{A}$.

Given an $\mathcal{I}$ -operator $O^{\mathcal{A}}$ on $\mathcal{A}$, we define three derived operators (functions) as follows:

- The **lifting of $O^{\mathcal{A}}$** , $\tilde{O}^{\mathcal{A}} : \mathcal{P}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})) \rightarrow \text{EqvFam}(\mathcal{A})$, is given, for all $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, by

$$\tilde{O}^{\mathcal{A}}(\mathcal{T}) = \bigcap \{O^{\mathcal{A}}(T) : T \in \mathcal{T}\};$$

- The **relativization of $O^{\mathcal{A}}$ to $\mathcal{I}$** , $\tilde{O}^{\mathcal{I}, \mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$, is given, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, by

$$\tilde{O}^{\mathcal{I}, \mathcal{A}}(T) = \bigcap \{O^{\mathcal{A}}(T') : T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} = \tilde{O}^{\mathcal{A}}(\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T);$$

- $O^{\mathcal{A}^{-1}} : \text{EqvFam}(\mathcal{A}) \rightarrow \mathcal{P}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}))$ is given, for all $\theta \in \text{EqvFam}(\mathcal{A})$, by

$$O^{\mathcal{A}^{-1}}(\theta) = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \theta \leq O^{\mathcal{A}}(T)\}.$$

Note that the lifting of the Leibniz operator $\Omega^{\mathcal{A}}$ on $\mathcal{A}$ is the Tarski operator $\tilde{\Omega}^{\mathcal{A}}$ on $\mathcal{A}$, whereas the relativization of the Leibniz operator on $\mathcal{A}$ is the Suszko operator $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}$ on $\mathcal{A}$.

Immediately from the definitions, we obtain the following:

Lemma 1554 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$.*

$$(a) \quad \tilde{O}^{\mathcal{I}, \mathcal{A}}(T) \leq O^{\mathcal{A}}(T), \text{ for all } T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A});$$

$$(b) \quad \tilde{O}^{\mathcal{A}}(\mathcal{T}) \leq O^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A}).$$

Proof: Obvious from the definitions. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, let there be given an $\mathcal{I}$ -operator $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$. We write

$$O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$$

and refer to this family as a **family of $\mathcal{I}$ -operators**.

Since $\mathcal{I}$ -operators are meant to abstract the operators of abstract algebraic logic, those properties that were studied in preceding chapters concerning the Leibniz operator play also a significant role when it comes to $\mathcal{I}$ -operators.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and

$$O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$$

an $\mathcal{I}$ -operator on $\mathcal{A}$.

- $O^{\mathcal{A}}$ is **order-preserving** or **monotone** if, for all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$T \leq T' \quad \text{implies} \quad O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T');$$

- $O^{\mathcal{A}}$ is **order-reflecting** or **reflective** if, for all $T, T' \in \text{ThFam}^{\mathcal{I}}(\mathcal{A})$,

$$O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad \text{implies} \quad T \leq T';$$

- $O^{\mathcal{A}}$ is **completely order reflecting** or **c-reflective** if, for all $\mathcal{T} \cup \{T'\} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\bigcap_{T \in \mathcal{T}} O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad \text{implies} \quad \bigcap \mathcal{T} \leq T'.$$

Some important characterizations are related to these properties.

Lemma 1555 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$.*

$$O^{\mathcal{A}} \text{ is monotone if and only if } O^{\mathcal{A}} = \tilde{O}^{\mathcal{I}, \mathcal{A}}.$$

Proof: Suppose, first, that $O^{\mathcal{A}}$ is monotone. Then, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{aligned} O^{\mathcal{A}}(T) &= \bigcap \{O^{\mathcal{A}}(T') : T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ &= \tilde{O}^{\mathcal{I}, \mathcal{A}}(T). \end{aligned}$$

If, conversely, $O^{\mathcal{A}} = \tilde{O}^{\mathcal{I}, \mathcal{A}}$, then, for all $T, T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $T \leq T'$, we get

$$\begin{aligned} O^{\mathcal{A}}(T) &= \tilde{O}^{\mathcal{I}, \mathcal{A}}(T) \\ &= \bigcap \{O^{\mathcal{A}}(T'') : T \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ &\leq \bigcap \{O^{\mathcal{A}}(T'') : T' \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\ &= \tilde{O}^{\mathcal{I}, \mathcal{A}}(T') \\ &= O^{\mathcal{A}}(T'). \end{aligned}$$

Therefore, $O^{\mathcal{A}}$ is monotone. ■

Lemma 1556 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$. $O^{\mathcal{A}}$ is c-reflective if and only if, for all $T, T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$\tilde{O}^{\mathcal{I}, \mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad \text{implies} \quad T \leq T'.$$

Proof: Assume, first, that $O^{\mathcal{A}}$ is c-reflective and let $T, T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{O}^{\mathcal{I}, \mathcal{A}}(T) \leq O^{\mathcal{A}}(T')$. Then, by definition, $\bigcap \{O^{\mathcal{A}}(T'') : T \leq T'' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})\} \leq O^{\mathcal{A}}(T')$. By c-reflectivity, $\bigcap \{T'' : T \leq T'' \in \mathbf{ThFam}^{\mathcal{I}}(\mathcal{A})\} \leq T'$, i.e., $T \leq T'$.

Suppose, conversely, that the displayed condition holds and let $\mathcal{T} \cup \{T'\} \subseteq \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\bigcap_{T \in \mathcal{T}} O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T')$. Then we get

$$\tilde{O}^{\mathcal{I}, \mathcal{A}}(\bigcap \mathcal{T}) \leq \bigcap_{T \in \mathcal{T}} O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T').$$

Hence, by the hypothesis, $\bigcap \mathcal{T} \leq T'$ and $O^{\mathcal{A}}$ is c-reflective. ■

We now show that the operators $\tilde{O}^{\mathcal{A}}$ and $O^{\mathcal{A}^{-1}}$, associated with a given $\mathcal{I}$ -operator $O^{\mathcal{A}}$, establish a Galois connection between the class $\mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}))$ of bundles of $\mathcal{I}$ -filters on $\mathcal{A}$ and the class $\mathbf{EqvFam}(\mathcal{A})$ of equivalence families on $\mathcal{A}$. This will yield several important consequences.

Proposition 1557 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$. The maps*

$$\begin{aligned} \tilde{O}^{\mathcal{A}} : \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) &\longrightarrow \mathbf{EqvFam}(\mathcal{A}) \\ \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) &\longleftarrow \mathbf{EqvFam}(\mathcal{A}) : O^{\mathcal{A}^{-1}} \end{aligned}$$

establish a Galois connection, where $\mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}))$ is ordered under the subclass relation and $\mathbf{EqvFam}(\mathcal{A})$ under signature-wise inclusion.

Proof: We must show that, for all $\mathcal{T} \subseteq \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\theta \in \mathbf{EqvFam}(\mathcal{A})$,

$$\mathcal{T} \subseteq O^{\mathcal{A}^{-1}}(\theta) \quad \text{iff} \quad \tilde{O}^{\mathcal{A}}(\mathcal{T}) \geq \theta.$$

In fact, we have

$$\begin{aligned} \mathcal{T} \subseteq O^{\mathcal{A}^{-1}}(\theta) &\quad \text{iff} \quad \theta \leq O^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T}, \\ &\quad \text{iff} \quad \theta \leq \bigcap \{O^{\mathcal{A}}(T) : T \in \mathcal{T}\} \\ &\quad \text{iff} \quad \theta \leq \tilde{O}^{\mathcal{A}}(\mathcal{T}). \end{aligned}$$

Thus $(\tilde{O}^{\mathcal{A}}, O^{\mathcal{A}^{-1}}) : \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) \rightleftarrows \mathbf{EqvFam}(\mathcal{A})$ is, in fact, a Galois connection. ■

Corollary 1558 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$.*

(a) *The operators*

$$\begin{aligned}\tilde{O}^{\mathcal{A}} &: \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) \rightarrow \mathbf{EqvFam}(\mathcal{A}) \\ O^{\mathcal{A}^{-1}} &: \mathbf{EqvFam}(\mathcal{A}) \rightarrow \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}))\end{aligned}$$

are order reversing;

(b) *The operators*

$$\begin{aligned}O^{\mathcal{A}^{-1}} \circ \tilde{O}^{\mathcal{A}} &: \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) \rightarrow \mathcal{P}(\mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})) \\ \tilde{O}^{\mathcal{A}} \circ O^{\mathcal{A}^{-1}} &: \mathbf{EqvFam}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})\end{aligned}$$

are closure operators;

(c) *The collection of fixed-points of $O^{\mathcal{A}^{-1}} \circ \tilde{O}^{\mathcal{A}}$ is the range of $O^{\mathcal{A}^{-1}}$ and the collection of fixed-points of $\tilde{O}^{\mathcal{A}} \circ O^{\mathcal{A}^{-1}}$ is the range of $\tilde{O}^{\mathcal{A}}$;*

(d) *$\tilde{O}^{\mathcal{A}}$ and $O^{\mathcal{A}^{-1}}$ restrict to mutually inverse order isomorphisms between the collections of fixed-points of $O^{\mathcal{A}^{-1}} \circ \tilde{O}^{\mathcal{A}}$ and of fixed-points of $\tilde{O}^{\mathcal{A}} \circ O^{\mathcal{A}^{-1}}$.*

Proof: Known facts about Galois connections. ■

We capture the elements described in Part (c) of Corollary 1558, by making the following definitions.

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and

$$O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$$

an $\mathcal{I}$ -operator on $\mathcal{A}$.

- A family $\mathcal{T} \subseteq \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$ is called $O^{\mathcal{A}}$ -**full** if $\mathcal{T} = O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{T}))$ if and only if $\mathcal{T} \in \mathbf{Ran}(O^{\mathcal{A}^{-1}})$;
- An equivalence family $\theta \in \mathbf{EqvFam}(\mathcal{A})$ is $O^{\mathcal{A}}$ -**full** if $\theta = \tilde{O}^{\mathcal{A}}(O^{\mathcal{A}^{-1}}(\theta))$ if and only if $\theta \in \mathbf{Ran}(\tilde{O}^{\mathcal{A}})$.

The following statements provide a justification of the terminology used.

Proposition 1559 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$.*

- (a) A collection $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is $O^{\mathcal{A}}$ -full if and only if it is the largest $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{O}^{\mathcal{A}}(\mathcal{D}) = \tilde{O}^{\mathcal{A}}(\mathcal{T})$;
- (b) An equivalence family $\theta \in \text{EqvFam}(\mathcal{A})$ is $O^{\mathcal{A}}$ -full if and only if it is the largest $\eta \in \text{EqvFam}(\mathcal{A})$, such that $O^{\mathcal{A}^{-1}}(\eta) = O^{\mathcal{A}^{-1}}(\theta)$.

Proof: We do Part (a). Part (b) can be proved analogously. Suppose, first, that $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is $O^{\mathcal{A}}$ -full and let $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{O}^{\mathcal{A}}(\mathcal{D}) = \tilde{O}^{\mathcal{A}}(\mathcal{T})$. Then, we have

$$\mathcal{D} \subseteq O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{D})) = O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{T})) = \mathcal{T}.$$

Suppose, conversely, that $\mathcal{T}$ is the largest among $\mathcal{D} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\tilde{O}^{\mathcal{A}}(\mathcal{D}) = \tilde{O}^{\mathcal{A}}(\mathcal{T})$ and let $T \in O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{T}))$. Then, by definition, $\tilde{O}^{\mathcal{A}}(\mathcal{T}) \leq O^{\mathcal{A}}(T)$. Hence, $\tilde{O}^{\mathcal{A}}(\mathcal{T} \cup \{T\}) = \tilde{O}^{\mathcal{A}}(\mathcal{T})$. By the maximality of $\mathcal{T}$, we conclude that $T \in \mathcal{T}$. This shows that $O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{T})) \subseteq \mathcal{T}$. Since the opposite inclusion always holds, we conclude that $\mathcal{T}$ is a fixed point of $O^{\mathcal{A}^{-1}} \circ \tilde{O}^{\mathcal{A}}$ and, hence, it is $O^{\mathcal{A}}$ -full. ■

We have the following consequences:

Corollary 1560 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$.

- (a) $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is $O^{\mathcal{A}}$ -full;
- (b) $\nabla^{\mathcal{A}}$ is $O^{\mathcal{A}}$ -full;
- (c) If $O^{\mathcal{A}}$ is monotone and $\mathcal{T}$ is $O^{\mathcal{A}}$ -full, then $\mathcal{T}$ is an upset in the poset $\mathcal{P}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}))$.

Proof: All three statements are direct consequences of Proposition 1559. ■

21.2 Congruential $\mathcal{I}$ -Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system. An $\mathcal{I}$ -operator $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ is called **congruential** if, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $O^{\mathcal{A}}(T) \in \text{ConSys}(\mathcal{A})$. Thus a congruential $\mathcal{I}$ -operator is an operator $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}(\mathcal{A})$.

Proposition 1561 Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system, $\theta \in \text{ConSys}(\mathcal{A})$ and $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$ the quotient natural transformation.

(a) $\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))$ and $\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) = \pi(\Omega^{\mathcal{A}^{-1}}(\theta))$;

(b) *The mappings*

$$\begin{aligned}\pi &: \text{SenFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{SenFam}(\mathcal{A}/\theta) \\ \pi^{-1} &: \text{SenFam}(\mathcal{A}/\theta) \rightarrow \text{SenFam}(\mathcal{A})\end{aligned}$$

restrict to mutually inverse order isomorphisms between $\Omega^{\mathcal{A}^{-1}}(\theta)$ and $\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$.

Proof:

(a) Suppose $T \in \Omega^{\mathcal{A}^{-1}}(\theta)$. Then $\theta \leq \Omega^{\mathcal{A}}(T)$. Hence θ is compatible with T , which implies, by Corollary 57, $\pi(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$. Suppose, conversely, that $T \in \pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))$. Then $\pi(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$ and, hence, by Corollary 57, $\pi^{-1}(\pi(T)) \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Therefore, T is compatible with θ , showing that $\theta \leq \Omega^{\mathcal{A}}(T)$. This gives $T \in \Omega^{\mathcal{A}^{-1}}(\theta)$.

The second equality of Part (a) is obtained from the first, using the surjectivity of $\langle I, \pi \rangle$.

(b) By Part (a), the mappings

$$\begin{aligned}\pi \upharpoonright_{\Omega^{\mathcal{A}^{-1}}(\theta)} &: \Omega^{\mathcal{A}^{-1}}(\theta) \rightarrow \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \\ \pi^{-1} \upharpoonright_{\text{FiFam}^{\mathcal{I}}(\mathcal{A})} &: \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \Omega^{\mathcal{A}^{-1}}(\theta)\end{aligned}$$

are well-defined. Moreover, they are clearly inverses of one another and order preserving. Thus, they establish an order isomorphism between $\Omega^{\mathcal{A}^{-1}}(\theta)$ and $\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$. ■

21.3 O -Classes and O -Filter Families

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and

$$O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$$

an $\mathcal{I}$ -operator on $\mathcal{A}$. For all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, the O -class of T , denoted $\llbracket T \rrbracket^O$, is the collection

$$\llbracket T \rrbracket^O = \Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T)) = \{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T')\}.$$

It turns out that this class forms a closure family on $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$.

Proposition 1562 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$. For all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\llbracket T \rrbracket^O$ is a closure family on $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$.*

Proof: First, observe that $\Omega^{\mathcal{A}}(\text{SEN}) = \nabla^{\mathcal{A}}$, whence $\text{SEN} \in \llbracket T \rrbracket^O$. Next, let $\{T^i : i \in I\} \subseteq \llbracket T \rrbracket^O$. Then, we have

$$O^{\mathcal{A}}(T) \leq \bigcap_{i \in I} \Omega^{\mathcal{A}}(T^i) \leq \Omega^{\mathcal{A}}\left(\bigcap_{i \in I} T^i\right).$$

So $\bigcap_{i \in I} T^i \in \llbracket T \rrbracket^O$ and $\llbracket T \rrbracket^O$ is a closure family on $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$. ■

Something even stronger is true in case $O^{\mathcal{A}}$ happens to be a congruential $\mathcal{I}$ -operator. In that case, the pair $\langle \mathcal{A}, \llbracket T \rrbracket^O \rangle$ turns out to be a full $\mathcal{I}$ -structure.

Proposition 1563 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}(\mathcal{A})$ a congruential $\mathcal{I}$ -operator on $\mathcal{A}$. For all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\langle \mathcal{A}, \llbracket T \rrbracket^O \rangle$ is a full $\mathcal{I}$ -structure.*

Proof: Let $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then $\llbracket T \rrbracket^O = \Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T))$. By hypothesis, $O^{\mathcal{A}}(T) \in \text{ConSys}(\mathcal{A})$. Thus, by Proposition 1561,

$$\llbracket T \rrbracket^O = \Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T)) = \pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\Omega^{\mathcal{A}}(T))),$$

where $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T)$ is the quotient natural transformation. Thus, by definition, $\langle \mathcal{A}, \llbracket T \rrbracket^O \rangle$ is a full $\mathcal{I}$ -structure. ■

As a corollary, we obtain the fact that $\llbracket T \rrbracket^O$ is a closure system on $\mathcal{A}$ and, therefore, $\langle \mathcal{A}, \llbracket T \rrbracket^O \rangle$ is a π -institution and not merely a π -structure.

Corollary 1564 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}(\mathcal{A})$ a congruential $\mathcal{I}$ -operator on $\mathcal{A}$. For all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, $\llbracket T \rrbracket^O$ is a closure system on $\text{FiFam}^{\mathcal{I}}(\mathcal{A})$.*

Proof: By Propositions 1563 and 1426. ■

Corollary 1564 justifies the following definition.

Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and

$$O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}(\mathcal{A})$$

a congruential $\mathcal{I}$ -operator on $\mathcal{A}$. For all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, the least element of the O -class of T is denoted by T^O :

$$T^O = \bigcap \llbracket T \rrbracket^O.$$

A $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is called an O -filter family if $T = T^O$. Note that, by Corollary 1564, an O -filter family must be an $\mathcal{I}$ -filter system.

The collection of all O -filter systems of $\mathcal{A}$ is denoted by $\text{FiFam}^{\mathcal{I}, O}(\mathcal{A})$.

Proposition 1565 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$. $O^{\mathcal{A}}$ is reflective (and, hence, injective) on $\mathbf{FiFam}^{\mathcal{I}, O}(\mathcal{A})$.*

Proof: Let $T, T' \in \mathbf{FiFam}^{\mathcal{I}, O}(\mathcal{A})$, such that $O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T')$. Then, $\llbracket T' \rrbracket^O \subseteq \llbracket T \rrbracket^O$. Therefore,

$$\begin{aligned} T &= T^O \quad (T \in \mathbf{FiFam}^{\mathcal{I}, O}(\mathcal{A})) \\ &= \bigcap \llbracket T \rrbracket^O \quad (\text{definition}) \\ &\leq \bigcap \llbracket T' \rrbracket^O \quad (\llbracket T' \rrbracket^O \subseteq \llbracket T \rrbracket^O) \\ &= T'^O \quad (\text{definition}) \\ &= T'. \quad (T' \in \mathbf{FiFam}^{\mathcal{I}, O}(\mathcal{A})) \end{aligned}$$

We conclude that $O^{\mathcal{A}}$ is reflective. ■

Proposition 1566 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{EqvFam}(\mathcal{A})$ a monotone $\mathcal{I}$ -operator on $\mathcal{A}$. Then the mapping $T \mapsto T^O$ is monotone, i.e., for all $T, T' \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$T \leq T' \quad \text{implies} \quad T^O \leq T'^O.$$

Proof: We have, for all $T, T' \in \mathbf{ThFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{aligned} T \leq T' &\text{ implies } O^{\mathcal{A}}(T) \leq O^{\mathcal{A}}(T') \quad (\text{hypothesis}) \\ &\text{ implies } \llbracket T' \rrbracket^O \subseteq \llbracket T \rrbracket^O \quad (\text{definitions of } \llbracket T \rrbracket^O, \llbracket T' \rrbracket^O) \\ &\text{ implies } T^O \leq T'^O. \quad (\text{definitions of } T^O, T'^O) \end{aligned}$$

So $T \mapsto T^O$ is a monotone mapping. ■

Proposition 1567 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system, $O^{\mathcal{A}} : \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \mathbf{ConSys}(\mathcal{A})$ a congruential $\mathcal{I}$ -operator on $\mathcal{A}$ and $T \in \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A})$. $T \in \mathbf{FiFam}^{\mathcal{I}, O}(\mathcal{A})$ if and only if $T/O^{\mathcal{A}}(T)$ is the least $\mathcal{I}$ -filter family of $\mathcal{A}/O^{\mathcal{A}}(T)$.*

Proof: By hypothesis, $O^{\mathcal{A}}(T) \in \mathbf{ConSys}(\mathcal{A})$. Consider the quotient natural transformation

$$\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/O^{\mathcal{A}}(T).$$

Since $\Omega^{\mathcal{A}^{-1}}(O^{\mathcal{A}}(T)) = \llbracket T \rrbracket^O$, we get, by Proposition 1561, that

$$\pi : \llbracket T \rrbracket^O \rightarrow \mathbf{FiFam}^{\mathcal{I}}(\mathcal{A}/O^{\mathcal{A}}(T))$$

is an order isomorphism. Thus, $T^O/O^{\mathcal{A}}(T)$ is the least $\mathcal{I}$ -filter family on $\mathcal{A}/O^{\mathcal{A}}(T)$. ■

21.4 Compatibility $\mathcal{I}$ -Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ an $\mathcal{I}$ -operator on $\mathcal{A}$. $O^{\mathcal{A}}$ is called a **compatibility $\mathcal{I}$ -operator** if, for all $T \in \text{ThFam}^{\mathcal{I}}(\mathcal{A})$,

$$O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T).$$

Clearly, $\Omega^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}(\mathcal{A})$ is the largest compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. If one assumes monotonicity, then this role is played by the Suszko operator instead:

Lemma 1568 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. For every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, the Suszko operator $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{ConSys}(\mathcal{A})$ is the largest monotone compatibility $\mathcal{I}$ -operator on $\mathcal{A}$.*

Proof: Suppose that $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ is a monotone compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. Then, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{aligned} O^{\mathcal{A}}(T) &= \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T) \quad (\text{by Lemma 1555}) \\ &= \bigcap \{ O^{\mathcal{A}}(T') : T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \} \quad (\text{by Definition}) \\ &\leq \bigcap \{ \Omega^{\mathcal{A}}(T') : T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \} \quad (\text{by Compatibility}) \\ &= \tilde{\Omega}^{\mathcal{I}, \mathcal{A}}(T). \quad (\text{by Definition}) \end{aligned}$$

So $\tilde{\Omega}^{\mathcal{I}, \mathcal{A}}$ is the largest monotone compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. ■

For compatibility $\mathcal{I}$ -operators, we have the following properties pertaining to O -classes and O -filter systems.

Lemma 1569 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ a compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. Then, for every $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$T \in [T]^O \quad \text{and} \quad T^O \leq T.$$

Proof: Let $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Since $O^{\mathcal{A}}$ is a compatibility $\mathcal{I}$ -operator, $O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T)$. Thus, by definition of $[T]^O$, we get $T \in [T]^O$. Moreover, since $T \in [T]^O$, we now get $T^O = \bigcap [T]^O \leq T$. ■

For monotone compatibility $\mathcal{I}$ -operators, we have the following properties.

Lemma 1570 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ a monotone compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. Then, for every $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$:*

- (a) $\text{FiFam}^{\mathcal{I}}(\mathcal{A})^T \subseteq \llbracket T \rrbracket^O$;
 (b) $\llbracket T \rrbracket^O = \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T$ iff $T = T^O$ iff $T \in \text{FiFam}^{\mathcal{I},O}(\mathcal{A})$.

Proof:

- (a) Suppose $T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then

$$\begin{aligned} O^{\mathcal{A}}(T) &\leq O^{\mathcal{A}}(T') \quad (\text{by Monotonicity}) \\ &\leq \Omega^{\mathcal{A}}(T'). \quad (\text{by Compatibility}) \end{aligned}$$

So, by definition of $\llbracket T \rrbracket^O$, $T' \in \llbracket T \rrbracket^O$.

- (b) The second equivalence is simply the definition of $\text{FiFam}^{\mathcal{I},O}(\mathcal{A})$. So it suffices to prove the first equivalence. Assume, first, that $\llbracket T \rrbracket^O = \text{FiFam}^{\mathcal{I},O}(\mathcal{A})$. Then, we have $T^O = \bigcap \llbracket T \rrbracket^O = \bigcap \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T = T$.

Assume, conversely, that $T = T^O$. Then, if $T' \in \llbracket T \rrbracket^O$, we get $T = T^O = \bigcap \llbracket T \rrbracket^O \leq T'$. Thus, $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. Since, by Part (a), the converse always holds, we get $\llbracket T \rrbracket^O = \text{FiFam}^{\mathcal{I}}(\mathcal{A})^T$. ■

In the case of compatibility $\mathcal{I}$ -operators, there are also close relationships between their classes and their filter families and those associated to the Leibniz operator. More precisely, we get:

Lemma 1571 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ a compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. Then, for every $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$:*

- (a) $\llbracket T \rrbracket^{\Omega} \subseteq \llbracket T \rrbracket^O$;
 (b) $T^O \leq T^{\Omega}$;
 (c) $\text{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \text{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})$.

Proof:

- (a) Let $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have

$$\begin{aligned} T' \in \llbracket T \rrbracket^{\Omega} &\text{ implies } \Omega^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad (\text{by Definition of } \llbracket T \rrbracket^{\Omega}) \\ &\text{ implies } O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad (\text{by Compatibility}) \\ &\text{ implies } T' \in \llbracket T \rrbracket^O. \quad (\text{by Definition of } \llbracket T \rrbracket^O) \end{aligned}$$

Thus, $\llbracket T \rrbracket^{\Omega} \subseteq \llbracket T \rrbracket^O$.

- (b) Using Part (a), we get $T^O = \bigcap \llbracket T \rrbracket^O \leq \bigcap \llbracket T \rrbracket^{\Omega} = T^{\Omega}$.

- (c) Assume $T' \in \text{FiFam}^{\mathcal{I},O}(\mathcal{A})$. Then, by definition, $T'^O = T'$. Thus, by Part (b), $T' \leq T'^{\Omega}$. Since, by Lemma 1569, $T'^{\Omega} \leq T'$, we get $T'^{\Omega} = T'$ and, therefore, $T' \in \text{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})$. We conclude that $\text{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \text{FiFam}^{\mathcal{I},\Omega}(\mathcal{A})$. ■

For monotone compatibility $\mathcal{I}$ -operators, we have similar relationships between their classes and their filter families and those associated to the Suszko operator.

Lemma 1572 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ a monotone compatibility $\mathcal{I}$ -operator on $\mathcal{A}$. Then, for every $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$:*

- (a) $\llbracket T \rrbracket^{\tilde{\Omega}^{\mathcal{I}}} \leq \llbracket T \rrbracket^O$;
- (b) $T^O \leq T^{\tilde{\Omega}^{\mathcal{I}}}$;
- (c) $\text{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \text{FiFam}^{\mathcal{I},\tilde{\Omega}^{\mathcal{I}}}(\mathcal{A})$.

Proof:

- (a) Let $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Then we have

$$\begin{aligned} T' \in \llbracket T \rrbracket^{\tilde{\Omega}^{\mathcal{I}}} & \text{ implies } \tilde{\Omega}^{\mathcal{I},\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad (\text{by Definition of } \llbracket T \rrbracket^{\tilde{\Omega}^{\mathcal{I}}}) \\ & \text{ implies } O^{\mathcal{A}}(T) \leq \Omega^{\mathcal{A}}(T') \quad (\text{by Lemma 1568}) \\ & \text{ implies } T' \in \llbracket T \rrbracket^O. \quad (\text{by Definition of } \llbracket T \rrbracket^O) \end{aligned}$$

$$\text{Thus, } \llbracket T \rrbracket^{\tilde{\Omega}^{\mathcal{I}}} \subseteq \llbracket T \rrbracket^O.$$

- (b) Using Part (a), we get $T^O = \bigcap \llbracket T \rrbracket^O \leq \bigcap \llbracket T \rrbracket^{\tilde{\Omega}^{\mathcal{I}}} = T^{\tilde{\Omega}^{\mathcal{I}}}$.
- (c) Assume $T' \in \text{FiFam}^{\mathcal{I},O}(\mathcal{A})$. Then, by definition, $T'^O = T'$. Thus, by Part (b), $T' \leq T'^{\tilde{\Omega}^{\mathcal{I}}}$. Since, by Lemma 1569, $T'^{\tilde{\Omega}^{\mathcal{I}}} \leq T'$, we get $T'^{\tilde{\Omega}^{\mathcal{I}}} = T'$ and, therefore, $T' \in \text{FiFam}^{\mathcal{I},\tilde{\Omega}^{\mathcal{I}}}(\mathcal{A})$. We conclude that $\text{FiFam}^{\mathcal{I},O}(\mathcal{A}) \subseteq \text{FiFam}^{\mathcal{I},\tilde{\Omega}^{\mathcal{I}}}(\mathcal{A})$. ■

21.5 Commuting $\mathcal{I}$ -Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle$:

$\mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism.

$$\begin{array}{ccc} & \mathbf{F} & \\ \langle F, \alpha \rangle \swarrow & & \searrow \langle G, \beta \rangle \\ \mathbf{A} & \xrightarrow{\langle H, \gamma \rangle} & \mathbf{B} \end{array}$$

Let, also $O^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$ and $O^{\mathcal{B}} : \text{FiFam}^{\mathcal{I}}(\mathcal{B}) \rightarrow \text{EqvFam}(\mathcal{B})$ be $\mathcal{I}$ -operators on $\mathcal{A}$ and on $\mathcal{B}$, respectively. We say that the pair $(O^{\mathcal{A}}, O^{\mathcal{B}})$ is **commuting** if, for all $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$O^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(O^{\mathcal{B}}(T')).$$

More generally, let $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ be a family of $\mathcal{I}$ -operators. We say that O is a **commuting family** if, for every pair $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ of $\mathbf{F}$ -algebraic systems, and every surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, the pair $(O^{\mathcal{A}}, O^{\mathcal{B}})$ is commuting.

A slightly more relaxed version, which will be of use to us later, is that of semi-commutation. We say that a family of $\mathcal{I}$ -operators $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ is a **semi-commuting family** if, for every pair $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ of $\mathbf{F}$ -algebraic systems, and every surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism, the pair $(O^{\mathcal{A}}, O^{\mathcal{B}})$ is commuting.

It turns out that semi-commutation is too restrictive when applied to compatibility $\mathcal{I}$ -operators, since there is only one semi-commuting family of compatibility $\mathcal{I}$ -operators, namely, the Leibniz operator.

Theorem 1573 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-commuting family of compatibility $\mathcal{I}$ -operators. Then $O = \Omega$.*

Proof: Let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ be an $\mathbf{F}$ -algebraic system and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. Consider the quotient morphism

$$\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\Omega^{\mathcal{A}}(T).$$

We get, using Compatibility,

$$O^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) \leq \Omega^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}.$$

So, we get $O^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T)) = \Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}$. Since, by hypothesis, O is a semi-commuting family, we now get

$$\begin{aligned} O^{\mathcal{A}}(T) &= O^{\mathcal{A}}(\pi^{-1}(T/\Omega^{\mathcal{A}}(T))) \\ &= \pi^{-1}(O^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}(T/\Omega^{\mathcal{A}}(T))) \\ &= \pi^{-1}(\Delta^{\mathcal{A}/\Omega^{\mathcal{A}}(T)}) \\ &= \Omega^{\mathcal{A}}(T). \end{aligned}$$

We conclude that $O = \Omega$. ■

In particular, we have

Corollary 1574 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The Suszko operator $\tilde{\Omega}^{\mathcal{I}}$ is semi-commuting if and only if $\tilde{\Omega}^{\mathcal{I}} = \Omega$.*

Proof: If $\tilde{\Omega}^{\mathcal{I}} = \Omega$, then, by Proposition 24, $\tilde{\Omega}^{\mathcal{I}}$ is commuting and, hence, semi-commuting. If conversely, $\tilde{\Omega}^{\mathcal{I}}$ is semi-commuting, then, by Theorem 1573, $\tilde{\Omega}^{\mathcal{I}} = \Omega$. ■

21.6 Coherent $\mathcal{I}$ -Operators

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a family of $\mathcal{I}$ -operators. Moreover, let $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$ be $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$.

- The morphism $\langle H, \gamma \rangle$ is said to be **O -compatible with T** if

$$\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(T);$$

- The morphism $\langle H, \gamma \rangle$ is said to be **O -compatible with $\mathcal{T}$** if

$$\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(T), \text{ for all } T \in \mathcal{T},$$

i.e., if and only if

$$\text{Ket}(\langle H, \gamma \rangle) \leq \tilde{O}^{\mathcal{A}}(\mathcal{T}).$$

For the Leibniz operator, we have

Corollary 1575 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A}, \mathcal{B}$ $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism. $\langle H, \gamma \rangle$ is Ω -compatible with T if and only if $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with T .*

Proof: We have $\langle H, \gamma \rangle$ is Ω -compatible with T if and only if, by definition, $\text{Ker}(\langle H, \gamma \rangle) \leq \Omega^{\mathcal{A}}(T)$ if and only if, by the compatibility of $\Omega^{\mathcal{A}}(T)$ with T , $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with T . ■

Moreover, for a family O of compatibility $\mathcal{I}$ -operators, we get

Corollary 1576 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a family of compatibility $\mathcal{I}$ -operators, $\mathcal{A}, \mathcal{B}$ $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. If $\langle H, \gamma \rangle$ is O -compatible with T , then:*

- (a) $\langle H, \gamma \rangle$ is Ω -compatible with T ;

(b) If H is an isomorphism, $T = \gamma^{-1}(\gamma(T))$;

(c) If H is an isomorphism, $O^{\mathcal{A}}(T) = \gamma^{-1}(\gamma(O^{\mathcal{A}}(T)))$.

Proof:

(a) We have

$$\begin{aligned} \text{Ker}(\langle H, \gamma \rangle) &\leq O^{\mathcal{A}}(T) \quad (\text{hypothesis}) \\ &\leq \Omega^{\mathcal{A}}(T). \quad (\text{by Compatibility}) \end{aligned}$$

Thus, $\langle H, \gamma \rangle$ is Ω -compatible with T .

(b) Suppose H is an isomorphism. By Part (a) and Corollary 1576, we get $\text{Ker}(\langle H, \gamma \rangle)$ is compatible with T . Therefore, $\gamma^{-1}(\gamma(T)) \leq T$. Since the reverse inclusion is always satisfied, we get $T = \gamma^{-1}(\gamma(T))$.

(c) Again the inclusion $O^{\mathcal{A}}(T) \leq \gamma^{-1}(\gamma(O^{\mathcal{A}}(T)))$ is always satisfied. So it suffices to show the reverse inclusion. So assume $\Sigma \in |\mathbf{Sign}|$, $\phi, \psi \in \text{SEN}(\Sigma)$, such that $\langle \phi, \psi \rangle \in \gamma_{\Sigma}^{-1}(\gamma_{\Sigma}(O_{\Sigma}^{\mathcal{A}}(T)))$. Thus, by definition, $\langle \gamma_{\Sigma}(\phi), \gamma_{\Sigma}(\psi) \rangle \in \gamma_{\Sigma}(O_{\Sigma}^{\mathcal{A}}(T))$. Therefore, there exist $\phi', \psi' \in \text{SEN}(\Sigma)$, with $\langle \phi', \psi' \rangle \in O_{\Sigma}^{\mathcal{A}}(T)$, such that $\langle \gamma_{\Sigma}(\phi), \gamma_{\Sigma}(\psi) \rangle = \langle \gamma_{\Sigma}(\phi'), \gamma_{\Sigma}(\psi') \rangle$. This shows that

$$\langle \phi, \phi' \rangle, \langle \psi, \psi' \rangle \in \text{Ker}_{\Sigma}(\langle H, \gamma \rangle) \leq O_{\Sigma}^{\mathcal{A}}(T).$$

Since $\langle \phi', \psi' \rangle \in O_{\Sigma}^{\mathcal{A}}(T)$ and $O^{\mathcal{A}}(T)$ is an equivalence family, we get, using symmetry and transitivity, that $\langle \phi, \psi \rangle \in O_{\Sigma}^{\mathcal{A}}(T)$. We conclude that $\gamma^{-1}(\gamma(O^{\mathcal{A}}(T))) \leq O^{\mathcal{A}}(T)$. ■

Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a family of $\mathcal{I}$ -operators.

- O is called **coherent** if, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}, \mathcal{B}$, every surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ and all $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\begin{aligned} \langle H, \gamma \rangle \text{ } O\text{-compatible with } \gamma^{-1}(T') \\ \text{implies } O^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(O^{\mathcal{B}}(T')). \end{aligned}$$

- O is called **semi-coherent** if, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}, \mathcal{B}$, every surjective morphism $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism, and all $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$,

$$\begin{aligned} \langle H, \gamma \rangle \text{ } O\text{-compatible with } \gamma^{-1}(T') \\ \text{implies } O^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(O^{\mathcal{B}}(T')). \end{aligned}$$

Clearly, if O is coherent, then it is also semi-coherent.

We define the **identity** $\mathcal{I}$ -operator

$$I = \{I^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\},$$

by letting, for all $\mathcal{A} \in \text{AlgSys}(\mathbf{F})$, $I^{\mathcal{A}} : \text{FiFam}^{\mathcal{I}}(\mathcal{A}) \rightarrow \text{EqvFam}(\mathcal{A})$, be given, for all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, by

$$I^{\mathcal{A}}(T) = \Delta^{\mathcal{A}}.$$

Lemma 1577 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The identity I is a coherent family of compatibility $\mathcal{I}$ -operators.*

Proof: It is clear that $I^{\mathcal{A}}$ is a compatibility $\mathcal{I}$ -operator, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$. So it suffices to prove coherence. To this end, let $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism and $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\text{Ker}(\langle H, \gamma \rangle) \leq I^{\mathcal{A}}(\gamma^{-1}(T')) = \Delta^{\mathcal{A}}$. Thus, we have $\text{Ker}(\langle H, \gamma \rangle) = \Delta^{\mathcal{A}}$. Now we get

$$\gamma^{-1}(I^{\mathcal{B}}(T')) = \gamma^{-1}(\Delta^{\mathcal{B}}) = \text{Ker}(\langle H, \gamma \rangle) = \Delta^{\mathcal{A}} = I^{\mathcal{A}}(\gamma^{-1}(T')).$$

Thus, I is a coherent family of compatibility $\mathcal{I}$ -operators. ■

Another example of a coherent $\mathcal{I}$ -operator is the Leibniz operator.

Lemma 1578 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system and $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$. The Leibniz operator Ω is a coherent family of compatibility operators.*

Proof: By definition Ω is a family of compatibility $\mathcal{I}$ -operators. For coherence, assume that $\mathcal{A}, \mathcal{B}$ are $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism and $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$. Since, by Proposition 24, $\Omega^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\Omega^{\mathcal{B}}(T'))$, we get that the coherence implication is trivially satisfied and, hence Ω is a coherent family of compatibility $\mathcal{I}$ -operators. ■

For semi-coherence of compatibility $\mathcal{I}$ -operators, we get the following characterization.

Lemma 1579 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a family of compatibility $\mathcal{I}$ -operators. O is semi-coherent if and only if, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}, \mathcal{B}$, all surjective morphisms $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism, and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, if $\langle H, \gamma \rangle$ is O -compatible with T , then $\gamma(O^{\mathcal{A}}(T)) = O^{\mathcal{B}}(\gamma(T))$.*

Proof: Suppose, first, that O is semi-coherent and let $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that

$$\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(T).$$

Then, by Corollary 1576, $\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(\gamma^{-1}(\gamma(T)))$. Applying semi-coherence gives

$$\begin{aligned} \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) &= O^{\mathcal{A}}(\gamma^{-1}(\gamma(T))) \quad (\text{by semi-coherence}) \\ &= O^{\mathcal{A}}(T). \quad (\text{by Corollary 1576}) \end{aligned}$$

By the surjectivity of $\langle H, \gamma \rangle$, $O^{\mathcal{B}}(\gamma(T)) = \gamma(O^{\mathcal{A}}(T))$.

Assume, conversely, that the condition in the statement holds. Let $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that

$$\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(\gamma^{-1}(T')).$$

Then, we get

$$\begin{aligned} O^{\mathcal{A}}(\gamma^{-1}(T')) &= \gamma^{-1}(\gamma(O^{\mathcal{A}}(\gamma^{-1}(T')))) \quad (\text{by Corollary 1576}) \\ &= \gamma^{-1}(O^{\mathcal{B}}(\gamma(\gamma^{-1}(T')))) \quad (\text{by hypothesis}) \\ &= \gamma^{-1}(O^{\mathcal{B}}(T')). \quad (\text{by surjectivity of } \langle H, \gamma \rangle) \end{aligned}$$

So O is a semi-coherent family of compatibility $\mathcal{I}$ -operators. ■

We also have the following alternative characterization for semi-coherence of compatibility $\mathcal{I}$ -operators.

Lemma 1580 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a family of compatibility $\mathcal{I}$ -operators. O is semi-coherent if and only if, for all $\mathbf{F}$ -algebraic systems $\mathcal{A}, \mathcal{B}$ and all surjective morphisms $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism,*

$$O^{\mathcal{A}^{-1}}(\text{Ker}(\langle H, \gamma \rangle)) = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}.$$

Proof: Suppose O is semi-coherent and let $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$.

- If $T \in O^{\mathcal{A}^{-1}}(\text{Ker}(\langle H, \gamma \rangle))$, then, by definition, $\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(T)$. Thus, by Lemma 1579, $\gamma(O^{\mathcal{A}}(T)) = O^{\mathcal{B}}(\gamma(T))$. Hence,

$$\gamma^{-1}(\gamma(O^{\mathcal{A}}(T))) = \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))).$$

Thus, by Corollary 1576, $O^{\mathcal{A}}(T) = \gamma^{-1}(O^{\mathcal{B}}(\gamma(T)))$.

- If $\gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)$, then we get $\text{Ker}(\langle H, \gamma \rangle) = \gamma^{-1}(\Delta^{\mathcal{B}}) \leq \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)$. Thus, $T \in O^{\mathcal{A}^{-1}}(\text{Ker}(\langle H, \gamma \rangle))$.

We conclude that $O^{\mathcal{A}^{-1}}(\text{Ker}(\langle H, \gamma \rangle)) = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}$.

Assume, conversely, that the condition of the statement holds. Let $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism and $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\text{Ker}(\langle H, \gamma \rangle) \leq O^{\mathcal{A}}(\gamma^{-1}(T'))$. Then $\gamma^{-1}(T') \in O^{\mathcal{A}^{-1}}(\text{Ker}(\langle H, \gamma \rangle))$, whence, by hypothesis,

$$\gamma^{-1}(O^{\mathcal{B}}(\gamma(\gamma^{-1}(T')))) = O^{\mathcal{A}}(\gamma^{-1}(T')).$$

By surjectivity of $\langle H, \gamma \rangle$, $\gamma^{-1}(O^{\mathcal{B}}(T')) = O^{\mathcal{A}}(\gamma^{-1}(T'))$ and, hence, O is a semi-coherent family of compatibility $\mathcal{I}$ -operators. ■

Next we show that semi-coherence of compatibility $\mathcal{I}$ -operators is preserved under relativization.

Proposition 1581 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$ -operators. Then*

$$\tilde{O}^{\mathcal{I}} = \{\tilde{O}^{\mathcal{I}, \mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$$

is also a semi-coherent family of compatibility $\mathcal{I}$ -operators.

Proof: It is easy to see that $\tilde{O}^{\mathcal{I}}$ is also a compatibility operator. We have, for every $\mathbf{F}$ -algebraic system $\mathcal{A}$ and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,

$$\begin{aligned} \tilde{O}^{\mathcal{I}, \mathcal{A}}(T) &= \cap \{O^{\mathcal{A}}(T') : T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} && \text{(definition)} \\ &\leq \cap \{\Omega^{\mathcal{A}}(T') : T \leq T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} && \text{(compatibility)} \\ &\leq \Omega^{\mathcal{A}}(T). && \text{(set theory)} \end{aligned}$$

Thus, $\tilde{O}^{\mathcal{I}}$ is indeed a compatibility $\mathcal{I}$ -operator.

For semi-coherence, assume $\mathcal{A}, \mathcal{B}$ are $\mathbf{F}$ -algebraic systems, $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism, and $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$, such that $\text{Ker}(\langle H, \gamma \rangle) \leq \tilde{O}^{\mathcal{I}, \mathcal{A}}(\gamma^{-1}(T'))$. We must show that

$$\tilde{O}^{\mathcal{I}, \mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\tilde{O}^{\mathcal{I}, \mathcal{B}}(T')).$$

Claim: We have

$$\{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(T') \leq T\} = \{\gamma^{-1}(T'') : T' \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})\}.$$

- Suppose $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\gamma^{-1}(T') \leq T$. Then, by Corollary 1576, $T = \gamma^{-1}(\gamma(T))$, where, by Corollary 56, $\gamma(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$. Moreover, by hypothesis and the surjectivity of $\langle H, \gamma \rangle$, $T' = \gamma(\gamma^{-1}(T')) \leq \gamma(T)$. This proves the left-to-right inclusion.

- Let $T' \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$. Then, by Corollary 55, we obtain $\gamma^{-1}(T'') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, by hypothesis, $\gamma^{-1}(T') \leq \gamma^{-1}(T'')$. This shows that the right-to-left inclusion also holds.

This proves the Claim. Now, based on the Claim, we reason as follows:

$$\begin{aligned}
 \gamma^{-1}(\tilde{O}^{\mathcal{I},\mathcal{B}}(T'')) &= \gamma^{-1}(\cap\{O^{\mathcal{B}}(T'') : T' \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})\}) \\
 &= \cap\{\gamma^{-1}(O^{\mathcal{B}}(T'')) : T' \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})\} \\
 &= \cap\{O^{\mathcal{A}}(\gamma^{-1}(T'')) : T' \leq T'' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})\} \\
 &\quad (\text{by Semi-Coherence of } O) \\
 &= \cap\{O^{\mathcal{A}}(T) : \gamma^{-1}(T') \leq T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})\} \\
 &\quad (\text{by the Claim}) \\
 &= \tilde{O}^{\mathcal{I},\mathcal{A}}(\gamma^{-1}(T')).
 \end{aligned}$$

Thus, $\tilde{O}^{\mathcal{I}}$ is indeed semi-coherent. ■

Proposition 1582 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a coherent family of compatibility $\mathcal{I}$ -operators. Let, also, $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism. For all $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{B}')$, such that $\langle H, \gamma \rangle$ is O -compatible with $\gamma^{-1}(T')$,*

$$\tilde{O}^{\mathcal{A}}(\gamma^{-1}(T')) = \gamma^{-1}(\tilde{O}^{\mathcal{B}}(T')).$$

Proof: We have

$$\begin{aligned}
 \gamma^{-1}(\tilde{O}^{\mathcal{B}}(T')) &= \gamma^{-1}(\cap\{O^{\mathcal{B}}(T') : T' \in \mathcal{T}'\}) \\
 &= \cap\{\gamma^{-1}(O^{\mathcal{B}}(T')) : T' \in \mathcal{T}'\} \\
 &= \cap\{O^{\mathcal{A}}(\gamma^{-1}(T')) : T' \in \mathcal{T}'\} \\
 &\quad (\text{hypothesis and coherence}) \\
 &= \cap\{O^{\mathcal{A}}(T) : T \in \gamma^{-1}(\mathcal{T}')\} \\
 &= \tilde{O}^{\mathcal{A}}(\gamma^{-1}(\mathcal{T}')).
 \end{aligned}$$
■

Proposition 1583 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ be a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$ -operators. Let, also, $\mathcal{A}, \mathcal{B}$ be $\mathbf{F}$ -algebraic systems and $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$ a surjective morphism, with H an isomorphism. For all $\mathcal{T} \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\langle H, \gamma \rangle$ is O -compatible with $\mathcal{T}$, $\gamma(\tilde{O}^{\mathcal{A}}(\mathcal{T})) = \tilde{O}^{\mathcal{B}}(\gamma(\mathcal{T}))$.*

Proof: By the hypothesis and Corollary 1576, we get that $\mathcal{T} = \gamma^{-1}(\gamma(\mathcal{T}))$. So exploiting Proposition 1582, we get

$$\begin{aligned}
 \gamma(\tilde{O}^{\mathcal{A}}(\mathcal{T})) &= \gamma(\tilde{O}^{\mathcal{A}}(\gamma^{-1}(\gamma(\mathcal{T})))) \\
 &= \gamma(\gamma^{-1}(\tilde{O}^{\mathcal{B}}(\gamma(\mathcal{T})))) \\
 &= \tilde{O}^{\mathcal{B}}(\gamma(\mathcal{T})).
 \end{aligned}$$
■

21.7 Semi-Coherence and Full Objects

We start by providing a characterization of the inverse operator associated with a semi-coherent family of compatibility $\mathcal{I}$ -operators.

Proposition 1584 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$ -operators. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ and all $\theta \in \text{ConSys}(\mathcal{A})$,*

$$\begin{aligned} O^{\mathcal{A}^{-1}}(\theta) &= \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^{\mathcal{A}}(T)\} \\ &= \pi^{-1}(\{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}), \end{aligned}$$

where $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$ denotes the quotient morphism.

Proof: We have by hypothesis and Lemma 1580,

$$O^{\mathcal{A}^{-1}}(\theta) = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^{\mathcal{A}}(T)\}.$$

For the second equality, if $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, such that $\pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^{\mathcal{A}}(T)$, then $T = \pi^{-1}(T/\theta)$ and, also,

$$\pi^{-1}(O^{\mathcal{A}/\theta}(T/\theta)) = O^{\mathcal{A}}(T) = O^{\mathcal{A}}(\pi^{-1}(T/\theta)).$$

This proves the left-to-right inclusion, since, by Corollary 57, we have $T/\theta \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$.

Assume, conversely, that $T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)$, such that $\pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))$. Then, by Corollary, 57, $\pi^{-1}(T') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and, moreover,

$$\pi^{-1}(O^{\mathcal{A}/\theta}(\pi^{-1}(T')/\theta)) = \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T')).$$

This proves the right-to-left-inclusion. ■

We now give a characterization of O -full $\mathcal{I}$ -classes for semi-coherent families of congruential compatibility $\mathcal{I}$ -operators.

Corollary 1585 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of congruential compatibility $\mathcal{I}$ -operators, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. $\mathcal{T}$ is $O^{\mathcal{A}}$ -full if and only if, for some surjective $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism, which may be taken to be the quotient morphism $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\tilde{O}(\mathcal{T})$,*

$$\mathcal{T} = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}.$$

Proof: Suppose $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ is $O^{\mathcal{A}}$ -full. By definition, $\mathcal{T} = O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{T}))$. Let $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\tilde{O}^{\mathcal{A}}(\mathcal{T})$ be the quotient morphism. Then we have $\mathcal{T} = O^{\mathcal{A}^{-1}}(\text{Ker}(\langle I, \pi \rangle))$ whence, by Proposition 1584,

$$\mathcal{T} = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \pi^{-1}(O^{\mathcal{A}/\tilde{O}^{\mathcal{A}}(\mathcal{T})}(\pi(T))) = O^{\mathcal{A}}(T)\}.$$

Assume, conversely, that $\mathcal{T} = \{T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}) : \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) = O^{\mathcal{A}}(T)\}$, for some surjective $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism. By Proposition 1584, $\mathcal{T} = O^{\mathcal{A}^{-1}}(\text{Ker}(\langle H, \gamma \rangle))$, whence $\mathcal{T} \in \text{Ran}(O^{\mathcal{A}^{-1}})$, showing that $\mathcal{T}$ is $O^{\mathcal{A}}$ -full. ■

Corollary 1586 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of congruential compatibility $\mathcal{I}$ -operators, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\mathcal{T} \subseteq \text{FiFam}^{\mathcal{I}}(\mathcal{A})$. $\mathcal{T}$ is $O^{\mathcal{A}}$ -full if and only if, for some $\theta \in \text{ConSys}(\mathcal{I})$, which can be taken to be $\tilde{O}^{\mathcal{A}}(\mathcal{T})$, and with $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$ the corresponding quotient morphism,*

$$\mathcal{T} = \pi^{-1}(\{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}).$$

Proof: Assume, first, that $\mathcal{T}$ is $O^{\mathcal{A}}$ -full. Then, by definition, we have $\mathcal{T} = O^{\mathcal{A}^{-1}}(\tilde{O}^{\mathcal{A}}(\mathcal{T}))$. Take $\theta = \tilde{O}^{\mathcal{A}}(\mathcal{T})$. Then $\mathcal{T} = O^{\mathcal{A}^{-1}}(\theta)$, whence, by Proposition 1584,

$$\mathcal{T} = \pi^{-1}(\{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}).$$

Assume, conversely, that $\mathcal{T}$ is given by the displayed expression above, for some $\theta \in \text{ConSys}(\mathcal{A})$ and $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$ the quotient morphism. Then, by Proposition 1584, $\mathcal{T} = O^{\mathcal{A}^{-1}}(\theta) \in \text{Ran}(O^{\mathcal{A}^{-1}})$ and, therefore, $\mathcal{T}$ is $O^{\mathcal{A}}$ -full, by definition. ■

Turning, next, to the full congruence systems, we obtain the following characterization.

Proposition 1587 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$ -operators, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\theta \in \text{ConSys}(\mathcal{A})$. θ is $O^{\mathcal{A}}$ -full if and only if*

$$\tilde{O}^{\mathcal{A}/\theta}(\{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}) = \Delta^{\mathcal{A}/\theta},$$

where $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$ is the quotient morphism.

Proof: Let $\mathcal{T}' = \{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta) : \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T'))\}$. Then $\langle I, \pi \rangle$ is compatible with $\pi^{-1}(\mathcal{T}')$, since, for all $T' \in \mathcal{T}'$,

$$\text{Ker}(\langle I, \pi \rangle) = \pi^{-1}(\Delta^{\mathcal{A}/\theta}) \leq \pi^{-1}(O^{\mathcal{A}/\theta}(T')) = O^{\mathcal{A}}(\pi^{-1}(T')).$$

Thus, by Propositions 1584 and 1582, θ is $O^{\mathcal{A}}$ -full if and only if

$$\theta = \tilde{O}^{\mathcal{A}}(O^{\mathcal{A}^{-1}}(\theta)) = \tilde{O}^{\mathcal{A}}(\pi^{-1}(\mathcal{T}')) = \pi^{-1}(\tilde{O}^{\mathcal{A}/\theta}(\mathcal{T}')).$$

Now, if θ is $O^{\mathcal{A}}$ -full, then we get, using the surjectivity of the quotient morphism,

$$\begin{aligned} \tilde{O}^{\mathcal{A}/\theta}(\mathcal{T}') &= \pi(\pi^{-1}(\tilde{O}^{\mathcal{A}/\theta}(\mathcal{T}'))) \\ &= \pi(\theta) = \Delta^{\mathcal{A}/\theta}. \end{aligned}$$

If, conversely, $\tilde{O}^{\mathcal{A}/\theta}(\mathcal{T}') = \Delta^{\mathcal{A}/\theta}$, then $\theta = \pi^{-1}(\Delta^{\mathcal{A}/\theta}) = \pi^{-1}(\tilde{O}^{\mathcal{A}/\theta}(\mathcal{T}'))$. Hence, by the equivalence detailed above, θ is $O^{\mathcal{A}}$ -full. $\blacksquare$

Since Ω is a semi-coherent family of compatibility $\mathcal{I}$ -operators, we now get

Corollary 1588 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$, $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$ an $\mathbf{F}$ -algebraic system and $\theta \in \text{ConSys}(\mathcal{A})$. Then*

$$\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta)),$$

where $\langle I, \pi \rangle : \mathcal{A} \rightarrow \mathcal{A}/\theta$ is the quotient morphism.

Proof: By Proposition 1584,

$$\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta') : \pi^{-1}(\Omega^{\mathcal{A}/\theta}(T')) = \Omega^{\mathcal{A}}(\pi^{-1}(T'))\}).$$

But, by Proposition 24, Ω is commuting and, hence,

$$\{T' \in \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta') : \pi^{-1}(\Omega^{\mathcal{A}/\theta}(T')) = \Omega^{\mathcal{A}}(\pi^{-1}(T'))\} = \text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta).$$

Therefore, $\Omega^{\mathcal{A}^{-1}}(\theta) = \pi^{-1}(\text{FiFam}^{\mathcal{I}}(\mathcal{A}/\theta))$. $\blacksquare$

21.8 The General Correspondence Theorem

Theorem 1589 (General Correspondence Theorem) *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$ -operators. Then, for all $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, all surjective morphisms $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism, and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, if $\langle H, \gamma \rangle$ is O -compatible with T , then γ induces an order isomorphism from $\llbracket T \rrbracket^{O^{\mathcal{A}}}$ onto $\llbracket \gamma(T) \rrbracket^{O^{\mathcal{B}}}$, with inverse γ^{-1} .*

Proof: Assume that $\langle H, \gamma \rangle$ is O -compatible with T . By Corollary 1576, $\langle H, \gamma \rangle$ is Ω -compatible with T . By the same Corollary and by Corollary 56, $T = \gamma^{-1}(\gamma(T))$ and $\gamma(T) \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$.

Suppose, next, that $T' \in \llbracket T \rrbracket^{O^A}$. Then, $\text{Ker}(\langle H, \gamma \rangle) \leq O^A(T) \leq \Omega^A(T')$. Again, based on Corollaries 1576 and 56, we get $\gamma^{-1}(\gamma(T')) = T'$ and $\gamma(T') \in \text{FiFam}^{\mathcal{I}}(\mathcal{B})$. Moreover, we get

$$\begin{aligned} O^{\mathcal{B}}(\gamma(T)) &= \gamma(O^A(T)) \quad (\text{by Lemma 1579}) \\ &\leq \gamma(\Omega^A(T')) \\ &= \Omega^{\mathcal{B}}(\gamma(T')). \quad (\text{by Lemma 1579}) \end{aligned}$$

Thus, $\gamma(T') \in \llbracket \gamma(T) \rrbracket^{O^{\mathcal{B}}}$.

Suppose, next, that $T'' \in \llbracket \gamma(T) \rrbracket^{O^{\mathcal{B}}}$. Then, we get $O^{\mathcal{B}}(\gamma(T)) \leq \Omega^{\mathcal{B}}(T')$. By Corollary 55, $\gamma^{-1}(T'') \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$ and by surjectivity, $\gamma(\gamma^{-1}(T'')) = T''$. Since $\langle H, \gamma \rangle$ is O -compatible with $T = \gamma^{-1}(\gamma(T))$, we get, using semi-coherence,

$$\begin{aligned} O^A(T) &= O^A(\gamma^{-1}(\gamma(T))) \\ &= \gamma^{-1}(O^{\mathcal{B}}(\gamma(T))) \\ &\leq \gamma^{-1}(\Omega^{\mathcal{B}}(T')) \\ &= \Omega^A(\gamma^{-1}(T')). \end{aligned}$$

Hence, $\gamma^{-1}(T'') \in \llbracket T \rrbracket^{O^A}$. We conclude that γ is a bijection from $\llbracket T \rrbracket^{O^A}$ onto $\llbracket \gamma(T) \rrbracket^{O^{\mathcal{B}}}$, with inverse γ^{-1} . But, clearly, both γ and γ^{-1} are order preserving functions, whence they establish an order isomorphism between these two ordered sets. ■

The General Correspondence Theorem has the following consequence concerning O -filter systems on different $\mathbf{F}$ -algebraic systems.

Corollary 1590 *Let $\mathbf{F} = \langle \text{Sign}^b, \text{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^A : A \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of compatibility $\mathcal{I}$ -operators. Then, for all $\mathbf{F}$ -algebraic systems $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, $\mathcal{B} = \langle \mathbf{B}, \langle G, \beta \rangle \rangle$, all surjective morphisms $\langle H, \gamma \rangle : \mathcal{A} \rightarrow \mathcal{B}$, with H an isomorphism, and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$, if $\langle H, \gamma \rangle$ is O -compatible with T , then*

$$T \in \text{FiFam}^{\mathcal{I}, O}(\mathcal{A}) \quad \text{iff} \quad \gamma(T) \in \text{FiFam}^{\mathcal{I}, O}(\mathcal{B}).$$

Proof: We have the following chain of equivalences:

$$\begin{aligned} T \in \text{FiFam}^{\mathcal{I}, O}(\mathcal{A}) &\text{ iff } T = T^O \\ &\text{ iff } T = \bigcap \llbracket T \rrbracket^{O^A} \\ &\text{ iff } \gamma(T) = \bigcap \llbracket \gamma(T) \rrbracket^{O^{\mathcal{B}}} \quad (\text{by Theorem 1589}) \\ &\text{ iff } \gamma(T) = \gamma(T)^O \\ &\text{ iff } \gamma(T) \in \text{FiFam}^{\mathcal{I}, O}(\mathcal{B}). \end{aligned}$$

Thus, the claim is established. ■

For semi-coherent congruential compatibility $\mathcal{I}$ -operators, we obtain a relation between the O -filter systems on an algebraic system and those on the quotient algebraic system.

Corollary 1591 *Let $\mathbf{F} = \langle \mathbf{Sign}^b, \mathbf{SEN}^b, N^b \rangle$ be an algebraic system, $\mathcal{I} = \langle \mathbf{F}, C \rangle$ a π -institution based on $\mathbf{F}$ and $O = \{O^{\mathcal{A}} : \mathcal{A} \in \text{AlgSys}(\mathbf{F})\}$ a semi-coherent family of congruential compatibility $\mathcal{I}$ -operators. Then, for every $\mathbf{F}$ -algebraic system $\mathcal{A} = \langle \mathbf{A}, \langle F, \alpha \rangle \rangle$, and all $T \in \text{FiFam}^{\mathcal{I}}(\mathcal{A})$,*

$$T^O / O^{\mathcal{A}}(T) = (T / O^{\mathcal{A}}(T))^O$$

and it is the least $\mathcal{I}$ -filter family on $\mathcal{A} / O^{\mathcal{A}}(T)$.
